# 1. Executive Summary

The U.S. Navy has been using High-frequency Acoustic Recording Packages (HARPs) to conduct passive acoustic monitoring in waters offshore of Virginia, North Carolina, and Florida to determine patterns of occurrence and distribution of cetacean species and anthropogenic sounds since 2007. The datasets discussed in this annual report came from seven HARP deployments made from 2012 through 2016: one near Norfolk Canyon, off the coast of Virginia (982 meter [m] depth) between June 2014 and April 2015; four off Cape Hatteras, North Carolina (850–980 m depths) between October 2012 and April 2016; and two off Jacksonville, Florida (800–806 m depths) between August 2014 and April 2016.

Each HARP dataset was manually scanned for marine mammal vocalizations and anthropogenic sounds using long-term spectral averages (LTSAs) and in some cases, automated detection algorithms. The effective frequency range of the HARP data (10 Hertz [Hz]–100 kilohertz [kHz]) was analyzed by focusing on three frequency bands: 10–1,000 Hz, 10–5,000 Hz, and 1–100 kHz. Only odontocete whistles are discussed in this report for the Norfolk Canyon deployment and three of the four Cape Hatteras deployments, as results from all other marine mammal analyses were previously presented in [Hodge et al. 2016](#).

Three baleen whale species were detected at the Cape Hatteras and Jacksonville sites: fin whale (*Balaenoptera physalus*), minke whale (*Balaenoptera acutorostrata*), and sei whale (*Balaenoptera borealis*). Fin whale calls showed peaks in occurrence during the winter months. Similarly, minke whale pulse trains showed a strong seasonal pattern at both sites. Peaks in detections of sei whale calls occurred between December and January at both sites, although the recordings at the Cape Hatteras site ended in mid-January.

Echolocation clicks from six known odontocete taxa were detected: *Kogia* sp., Risso's dolphin (*Grampus griseus*), sperm whale (*Physeter macrocephalus*), Cuvier's beaked whale (*Ziphius cavirostris*), Gervais' beaked whale (*Mesoplodon europaeus*), and Blainville's beaked whale (*Mesoplodon densirostris*). The only identified delphinid clicks detected at both sites were those of Risso's dolphins; they occurred in low numbers at Cape Hatteras but quite frequently in Jacksonville, with peaks in detections at night and between April and July 2015. *Kogia* sp. clicks were detected throughout all of the recordings from these two locations, with more detections at the Jacksonville site. Sperm whale clicks were detected frequently at Cape Hatteras and more intermittently at Jacksonville. Cuvier's beaked whale clicks were very rarely detected at the Jacksonville site but were the most abundant beaked whale click type found at Cape Hatteras, with increases in detections between September and December and possibly April and May at that site. Gervais' beaked whale clicks were detected a few times at the Jacksonville site and often at the Cape Hatteras site, with fewer detections in September and October at Cape Hatteras. Blainville's beaked whale clicks were detected at both sites but very rarely. Finally, odontocete clicks and whistles that could not be assigned to species were detected throughout all recordings.

Anthropogenic sounds were also detected at both sites. Included in this report are mid-frequency active (MFA) sonar, low-frequency active (LFA) sonar greater than 500 Hz, high-frequency active (HFA) sonar, and airgun detections. MFA sonar was detected throughout the

1 two recordings reported here that had data in that frequency range available. The Jacksonville  
2 dataset had peaks in MFA sonar detections in September 2014 and January 2015. LFA sonar  
3 greater than 500 Hz was detected on only one day in Cape Hatteras. HFA sonar was detected  
4 on only one day in Jacksonville. Airguns were detected throughout the recording made at Cape  
5 Hatteras, with peaks in detections in April 2015 and between June and September 2015.

## 2. Introduction and Background

In October 2005, the United States (U.S.) Department of the Navy proposed the installation of an Undersea Warfare Training Range (USWTR) in one of four sites along the Atlantic coast, for the purpose of anti-submarine warfare training using mid-frequency tactical sonar (1–10 kHz) in outer continental shelf waters. The initial preferred site for the USWTR was Onslow Bay, North Carolina. As part of a multi-institutional monitoring plan for Onslow Bay, an acoustic monitoring effort, funded by the U.S. Atlantic Fleet, was initiated in 2007 by Duke University with assistance from Scripps Institution of Oceanography (SIO). In 2008, the preferred site was changed to Jacksonville, Florida. While acoustic monitoring continued in Onslow Bay, it also began in Jacksonville in 2009, once again led by Duke University with assistance from SIO. In broad support of Atlantic Fleet Training and Testing acoustic monitoring later expanded to an area off Cape Hatteras, North Carolina (2012), and near Norfolk Canyon, off the coast of Virginia (2014). During 2016, passive acoustic data were collected at the Jacksonville, Cape Hatteras, and Norfolk Canyon sites using autonomous bottom-mounted recorders. The primary objectives of the passive acoustic monitoring program are as follows:

- 1) Determine the patterns of occurrence of marine mammal species at each monitoring site;
- 2) Compare patterns of occurrence to better understand distributional patterns; and.
- 3) Document species-specific characteristics of the vocalizations of marine mammal species in each area.

## 3. General Methods

### 3.1 Bottom-mounted Recorders

To collect time-series of acoustic data in all three survey areas, autonomous High-frequency Acoustic Recording packages (HARPs; Wiggins and Hildebrand 2007) were utilized. The HARP data-logging system includes a 16-bit analog-to-digital converter; a hydrophone suspended approximately 10–12 m (large mooring, see **Figure 1**), approximately 22 m (small mooring, see **Figure 2**), or approximately 20 m (compact small mooring, see **Figure 3**) above the seafloor; an acoustic release system; ballast weights; and flotation (**Figures 1 through 3**). The data-loggers are capable of sampling up to 200 kHz and can be set to record continuously or on a duty cycle to accommodate variable deployment durations. These instruments combine high- and low-frequency hydrophone elements to detect the vocalizations of both odontocete and mysticete cetaceans. The units sample at rates high enough to capture the clicks of many odontocetes.

### 3.2 Summary of Deployments

HARPs have been deployed 10 times in Onslow Bay, 16 times in Jacksonville, six times in Cape Hatteras, and twice at the Norfolk Canyon site (**Table 1**). There were two occasions during which two HARPs were recording concurrently at different sites in Onslow Bay, and there were five occasions during which two HARPs were recording concurrently at different sites in Jacksonville (**Table 1**). **Table 1** includes location, depth, deployment and retrieval dates,

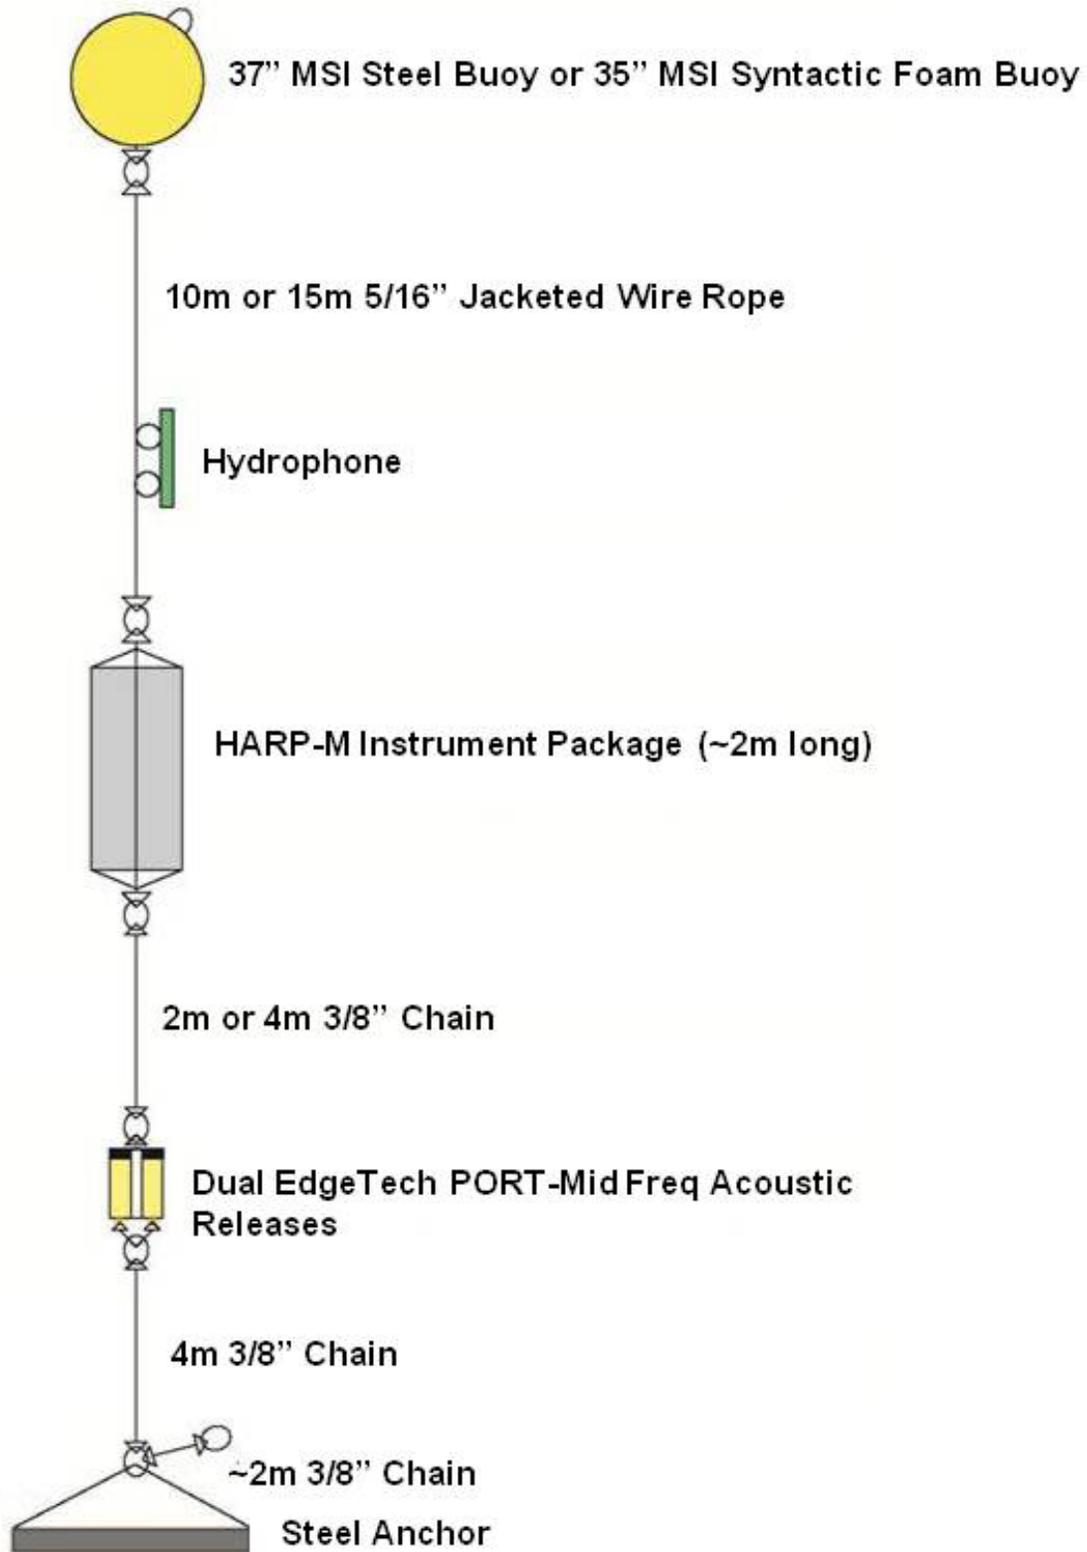

- 1 recording dates, information on duty cycle, mooring type, status of analysis, and reports
- 2 available. All HARPs sampled at 200 kHz.
- 3 Individual technical reports and detailed analyses of all HARP deployments are available
- 4 through the Navy's Marine Species Monitoring Program web portal [PAM Deployment Explorer](#)
- 5 and [Reading Room](#)

Notes: All HARPs sampled at 200 kHz. For Mooring Type: csm = compact small mooring. For Status of Analysis: HF = high-frequency (> 1 kHz) analysis completed; LF = low-frequency (< 1 kHz) analysis completed; M = LF analysis completed only for minke whales; IP = analysis in progress; N/A = not applicable - data are not yet available for analysis. For Report Available: T = technical report; D = detailed report; N/A = not applicable, because HARP is still in the field. Key: JAX = Jacksonville Range Complex; m = meter(s); USWTR = Undersea Warfare Training Range. \* = represents the initial duty cycle, but instrument recorded continuously starting 01 January 2008. \*\* = represents end of normal recording – there were four more files on four different days between 26DEC14 and 15JAN15 (skipping caused by disk error issue).

3 not drawn to scale.

### 1 3.3 Data Analysis

2 HARP data require processing prior to analysis, including backing up data in original format,  
3 converting data to .wav format, decimating .wav data by a factor of 20 or 100 to aid in detection of  
4 baleen whales and anthropogenic sounds, and creating LTSAs. The amount of data collected by  
5 HARPs is impractical to analyze manually, so data were compressed for visual overview by using a  
6 *MATLAB*-based acoustic analysis program called *Triton* (Hildebrand Lab at SIO, La Jolla, CA) to  
7 create LTSAs from the .wav files, which allowed for rapid review of the data. LTSAs are effectively  
8 compressed spectrograms created using the Welch algorithm (Welch 1967) by coherently  
9 averaging 500 spectra created from 2000-point, 0 percent-overlapped, Hann-windowed data and  
10 displaying these averaged spectra sequentially over time.

11 Each HARP dataset was manually scanned for marine mammal vocalizations and anthropogenic  
12 sounds using the “logger” version of *Triton* (Hildebrand Lab at SIO, La Jolla, CA). Automated  
13 computer algorithm detectors were also used to analyze the data. The effective frequency range of  
14 the HARP data (10 Hz–100 kHz) was analyzed by focusing on three frequency bands: 10–1,000  
15 Hz, 10–5,000 Hz, and 1–100 kHz. The resulting resolutions of the LTSAs were as follows:

- 16 • Low-frequency LTSA (LF-LTSA), for the data decimated by a factor of 100: 5 seconds [s] in  
17 time and 1 Hz in frequency (10–1,000 Hz band)
- 18 • Mid-frequency LTSA (MF-LTSA), for the data decimated by a factor of 20: 5 s in time and  
19 10 Hz in frequency (10–5,000 Hz band)
- 20 • High-frequency LTSA (HF-LTSA), for the data not decimated: 5 s in time and 100 Hz in  
21 frequency (1-100 kHz band).

22 The maximum frequency of the LF-LTSAs is 1 kHz, preceded by an energy roll-off associated with  
23 the low-pass filter used for decimation. These LF-LTSAs are optimized for detection of very low  
24 frequency signals, such as fin whale calls. Mid-frequency signals with energy generally above ~500  
25 Hz (e.g., low-frequency active (LFA) sonar) or signals that are difficult to identify without including  
26 the higher frequency information (e.g., ship noise, airguns) were detected in the MF-LTSAs. During  
27 manual inspection of LTSAs, the LF-LTSAs were set to display frequencies between 1–300 Hz,  
28 while the MF-LTSAs and HF-LTSAs were set to display the entire bandwidth available. Thus, the  
29 LF-LTSAs were inspected for sounds produced by blue (*Balaenoptera musculus*), fin  
30 (*Balaenoptera physalus*), sei (*Balaenoptera borealis*), Bryde’s (*Balaenoptera edeni*), minke  
31 (*Balaenoptera acutorostrata*), and North Atlantic right whales (*Eubalaena glacialis*). Although one  
32 of the Jacksonville datasets presented in this report was also inspected for the 5-pulse signal found  
33 during previous deployments off of Jacksonville, Florida (Debich et al. 2013), this sound is now  
34 thought to come from a fish and therefore is no longer being searched for in any of the datasets.  
35 The MF-LTSAs were inspected for humpback whale (*Megaptera novaeangliae*) calls, shipping,  
36 explosions, airguns, underwater communications, LFA sonar above 500 Hz, and mid-frequency  
37 active (MFA) sonar. Non-decimated LTSAs were inspected for the remaining odontocete sounds.  
38 LF sounds were analyzed in hourly bins; MF and HF sounds were analyzed in 1-minute bins  
39 (odontocete whistles, sperm whale clicks, *Kogia* clicks, beaked whale clicks) or 5-minute bins  
40 (delphinid clicks). Bin sizes (hourly, 1-minute, and 5-minute) represent the metric of animal  
41 presence, being an efficient way to estimate presence or absence within a large dataset, and were

1 chosen depending on estimated call detection range and average swim speeds, two parameters  
2 that indicate how long an animal is likely in the area. Thus, one hour granularity was used as an  
3 approximation for baleen whales, which have larger estimated call detection ranges (> 10 km) and  
4 lower average swim speeds than odontocetes, which were analyzed using 1- or 5-minute  
5 granularity. Vocalizations were assigned to species when possible. For North Atlantic right whale  
6 calls, the data were only examined for up-calls. Information on the detections of shipping,  
7 explosions, and underwater communications is not reported here but can be found in Frasier et al.  
8 ([2016](#), [2017](#)), and Varga et al. ([2017](#)).

9 Detections of many sounds were made by manually scanning LTSAs. However, automated  
10 detectors were used for some calls, including fin whale 20-Hz calls (for the Cape Hatteras dataset  
11 only) and humpback whale calls, as well as delphinid, *Kogia* sp., and beaked whale echolocation  
12 signals.

13 For all datasets, humpback whale call detection effort was automated using a power-law detector  
14 (Helble et al. 2012). After the generalized power-law algorithm was applied, a trained analyst  
15 verified the accuracy of the detected signals. No effort was made to separate song and non-song  
16 calls.

17 Fin whale 20-Hz calls were detected using an energy detection method, which used a difference in  
18 acoustic energy between signal and noise, calculated from a 5-s LTSA with 1-Hz resolution. The  
19 frequency at 22 Hz was used as the signal frequency, while noise was calculated as the average  
20 energy between 10 and 34 Hz. The resulting ratio is termed the fin whale acoustic index and is  
21 reported as a daily average. All calculations were performed on a decibel scale.

22 Three steps were involved in the classification of *Kogia* clicks. First, the clicks with energy between  
23 70 and 100 Hz and without energy in lower frequency bands were identified. Then, an expert  
24 system classified these clicks based on spectral characteristics, and finally an analyst verified all  
25 echolocation click bouts manually as *Kogia* clicks.

26 Delphinid echolocation clicks were detected using a modified version of a Teager energy detector  
27 (Soldevilla et al. 2008, Roch et al. 2011). Events were reviewed manually to remove false  
28 detections. LTSAs were then manually examined to identify reoccurring echolocation click types.  
29 Clicks were manually classified into separate click types based on characteristics such as inter-  
30 click interval, spectral peaks/troughs, and peak frequency. Classification was carried out by  
31 comparison to species-specific spectral characteristics from HARP recordings in the Gulf of Mexico  
32 (Frasier 2015). See Debich et al. ([2016](#)) for a more detailed description of the above analysis  
33 methods.

34 Beaked whale echolocation signals were detected with an automated method for all sites. The  
35 detection of these signals began with the same initial automated detection steps described in detail  
36 in Debich et al. ([2014](#)) to find 75-s recording segments containing potential beaked whale  
37 frequency-modulated pulses. A Teager Kaiser energy detector (Roch et al. 2011) was used to find  
38 echolocation signals, and criteria based on peak and center frequency, duration, and sweep rate  
39 were used to discriminate between delphinid and beaked whale signals ([Debich et al. 2014](#)). Then,  
40 additional criteria based on the shape and duration of the signal envelope were applied to reduce  
41 the high number of false detections of non-beaked whale clicks. All detected signals with a signal

1 envelope increasing after 20 sample points, and remaining above a 50 percent energy threshold  
2 for at least 19 sample points but no greater than 70 sample points, were kept; signals not meeting  
3 these criteria were removed from analysis. The remaining detections were grouped into detection  
4 events, with detections separated by no more than 5 minutes considered to be a single event. A  
5 final computer-assisted manual classification step was implemented where each detected event  
6 was given a species label by a trained analyst, and any remaining false detections were rejected  
7 (as in Baumann-Pickering et al. 2013).

8 Explosions were also detected automatically, using a matched filter detector described in further  
9 detail in Debich et al. ([2015](#)).

10 Airguns were detected automatically and manually verified following the method for explosion  
11 detections in Debich et al. ([2016](#)). This approach produces more precise airgun counts and  
12 imposes a consistent detection threshold.

## 1 4. Norfolk Canyon

### 2 4.1 Methods

#### 3 Data Collection

4 The compact small mooring design HARP that was deployed in Norfolk Canyon at a depth of  
 5 968 m at 37.1652° N, 74.4666° W (Norfolk Canyon Site A) on 30 April 2016, is expected to be  
 6 retrieved in June 2017 (**Table 2, Figure 4**). A schematic diagram of the HARP mooring for this  
 7 deployment is shown in **Figure 5**. The HARP is sampling continuously at 200 kHz.

8 **Table 2. Norfolk Canyon HARP deployments and analyses included in this report.**

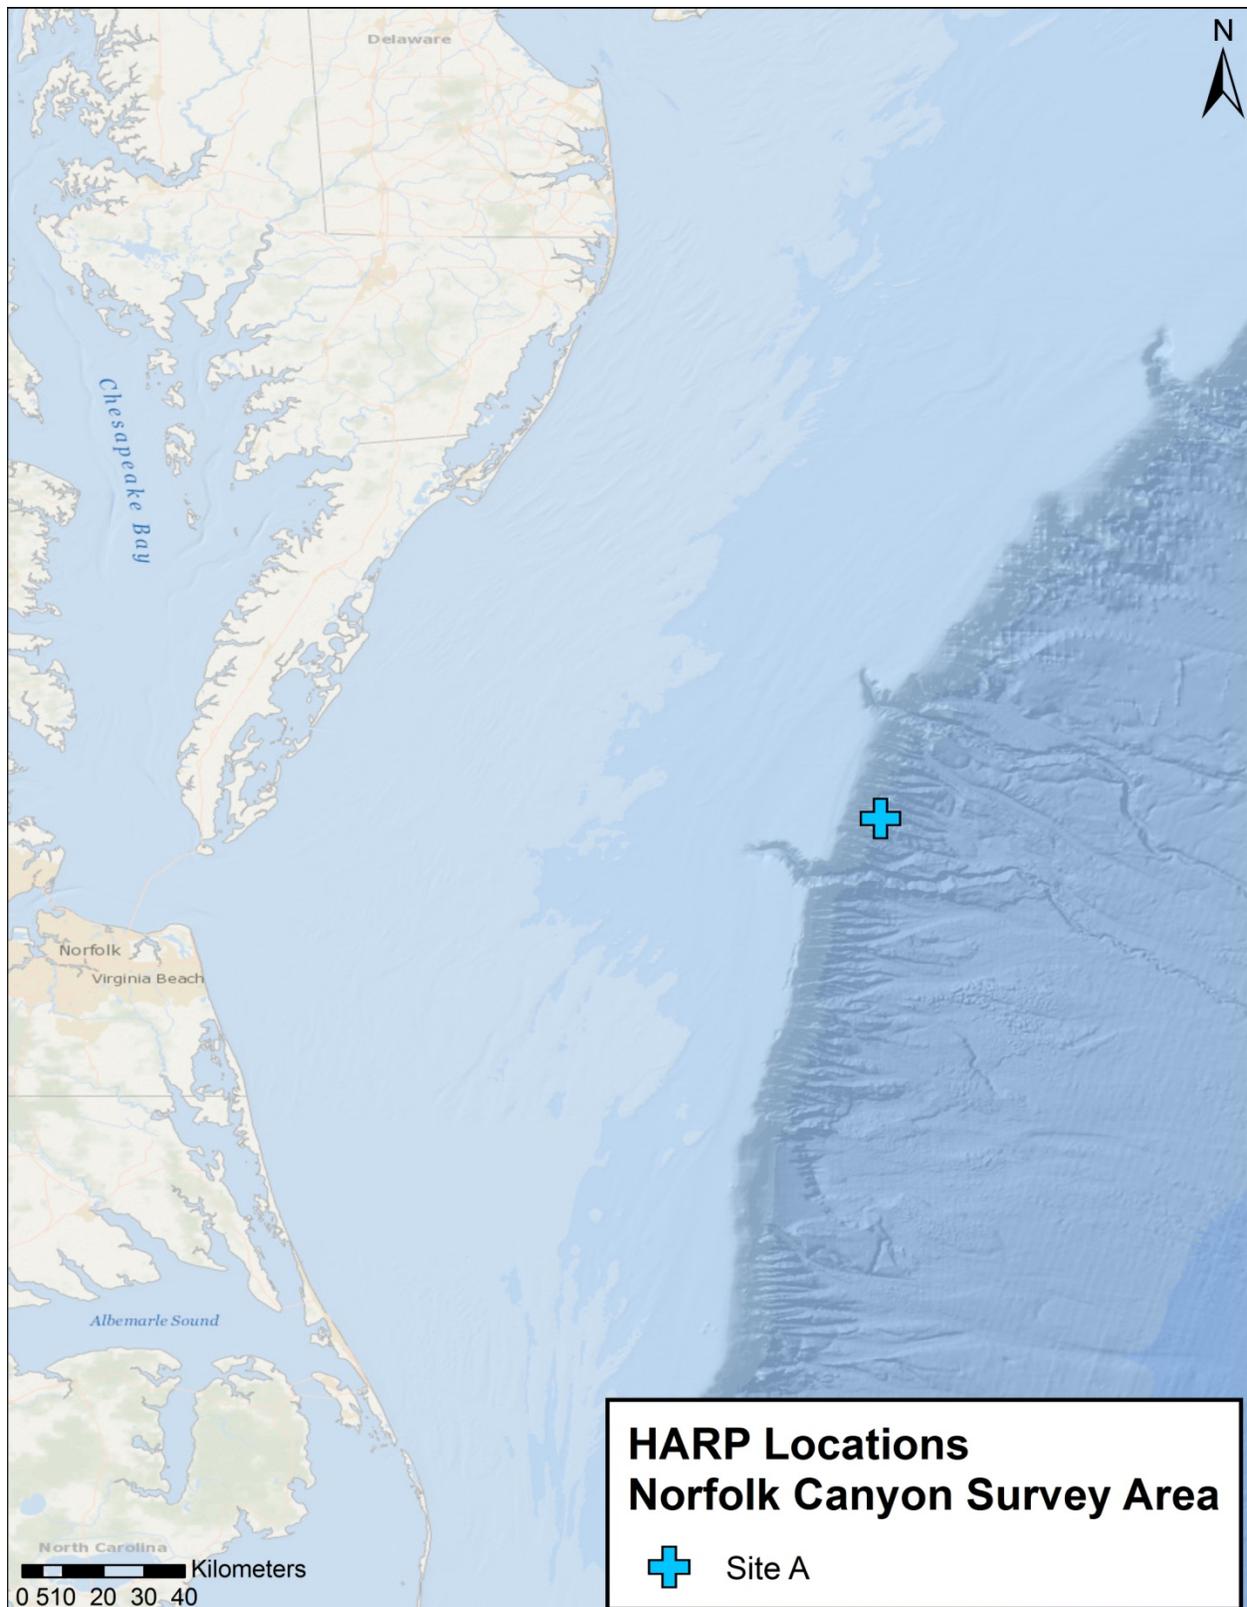

Site	Deployment Date	Retrieval Date	Recording Start Date	Recording End Date	Latitude (N)	Longitude (W)	Depth (m)	Sampling Rate	Duty Cycle
01A	19-Jun-14	7-Apr-15	19-Jun-14	05-Apr-15	37.1662	74.4669	982	200 kHz	continuous
02A	30-Apr-16	N/A	30-Apr-16	N/A	37.1652	74.4666	968	200 kHz	continuous

#### 9 Data Analysis

10 The June 2014–April 2015 Norfolk Canyon Site A deployment yielded 6,951 hours of recording  
 11 time over 290 days of recording (**Table 2**) and analysis of marine mammal and anthropogenic  
 12 sounds was reported on in Hodge et al. ([2016](#)) and Debich et al. ([2016](#)), except for odontocete  
 13 whistles, which will be presented here.

#### 14 Data Quality

15 Highly stereotyped broadband digital errors ('glitches') were found in the June 2014–April 2015  
 16 Norfolk Canyon dataset. These glitches were short in duration (between 100 microseconds [ $\mu$ s]  
 17 and 10 milliseconds [ms]) and started in the second half of the dataset, increasing in occurrence  
 18 once they appeared. It is believed that the glitches do not significantly impact the resulting data  
 19 analysis.

## 5. Cape Hatteras, North Carolina

### 5.1 Methods

#### Data Collection

The compact small mooring HARP deployed on 6 April 2015 at 35.34218° N, 74.85726° W (Cape Hatteras Site A) in approximately 980 m was retrieved on 29 April 2016 (Table 4, Figure 8). The HARP was redeployed that same day at the same site (35.3057° N, 74.8776° W) in approximately 1,020 m and is still currently in the field, with an expected retrieval date in June 2017 (Table 4, Figure 8). The HARP was programmed to sample continuously at 200 kHz for both deployments. A schematic diagram of the HARP mooring for these deployments is shown in Figure 9.

Table 4. Cape Hatteras HARP deployments and analyses included in this report.

Site	Deployment Date	Retrieval Date	Recording Start Date	Recording End Date	Latitude (N)	Longitude (W)	Depth (m)	Sampling Rate	Duty Cycle
02A	09-Oct-12	29-May-13	09-Oct-12	9-May-13	35.3406	74.8559	970	200 kHz	continuous

06A	29-Apr-16	N/A	29-Apr-16	N/A	35.3057	74.8776	~1020	200 kHz	continuous

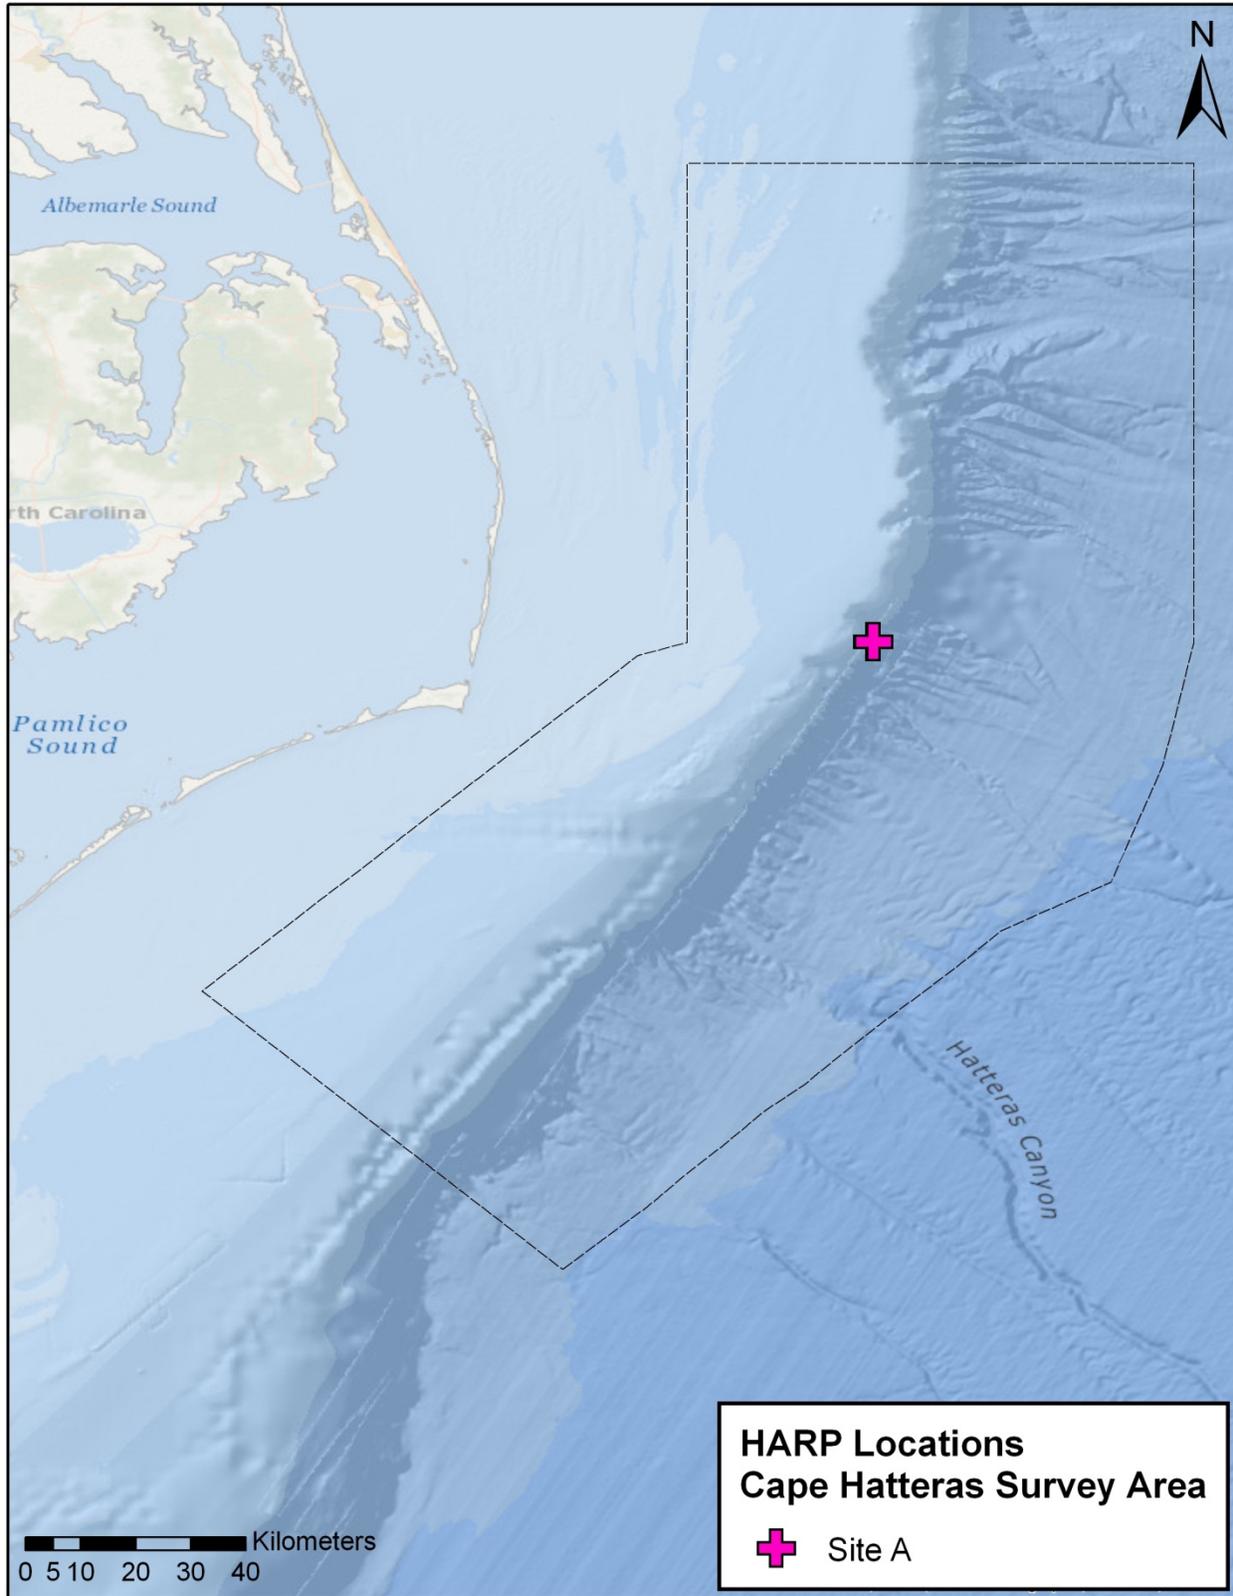

#### Data Analysis

Four datasets from deployments at Cape Hatteras Site A have been analyzed for marine mammal and anthropogenic sounds. For three of these datasets (October 2012–May 2013 dataset, May 2013–March 2014 dataset, and the May–December 2014 dataset), all sounds except for odontocete whistles were reported in Hodge et al. (2016) and Debich et al. (2016). The fourth dataset was from the April 2015–April 2016 deployment that yielded 6,948 hours of recording time over 290 days.

#### Data Quality

Highly stereotyped broadband digital errors ('glitches') were found in the October 2012–May 2013 and the May 2013–March 2014 Cape Hatteras datasets. These glitches were short in duration (between 100  $\mu$ s and 10 ms) and started in the second half of both datasets, increasing in occurrence once they appeared. To repair the glitches, the data were overwritten using a detector calibrated to the observed amplitude and duration of the glitches. This process does not overwrite any real broadband signals in the data. It is believed that neither the glitches nor the repair process significantly impacted the resulting data analysis.

The May–December 2014 Cape Hatteras deployment experienced disk error issues, causing skipping in the recorded data beginning on December 11. These disk error issues resulted in only four more 75-s files written on four different days between 26 December 2014 and 15 January 2015, which were not included in the analysis.

## 1 5.2 Results

2 These results are a summary of Debich et al. (2016) and Frasier et al. (2017). Monthly averages  
3 of underwater ambient noise during the April 2015–January 2016 dataset from Cape Hatteras  
4 Site A are shown in **Figure 10**. **Table 5** gives details on the detected odontocete whistles during  
5 the October 2012–May 2013, May 2013–March 2014, and May–December 2014 datasets, and  
6 **Figures 11 through 12** show the daily occurrence patterns of these whistles, separated by  
7 frequency. **Table 8** summarizes the detected and identified marine mammal vocalizations  
8 during the April 2015–January 2016 dataset. **Figures 13 through 24** show the daily occurrence  
9 patterns for the different marine mammal groups (classified to species when possible) and  
10 **Figure 25** shows the occurrence of MFA sonar and LFA sonar at Cape Hatteras Site A for the  
11 April 2015–January 2016 data set. **Figure 26** shows the occurrence of airguns.

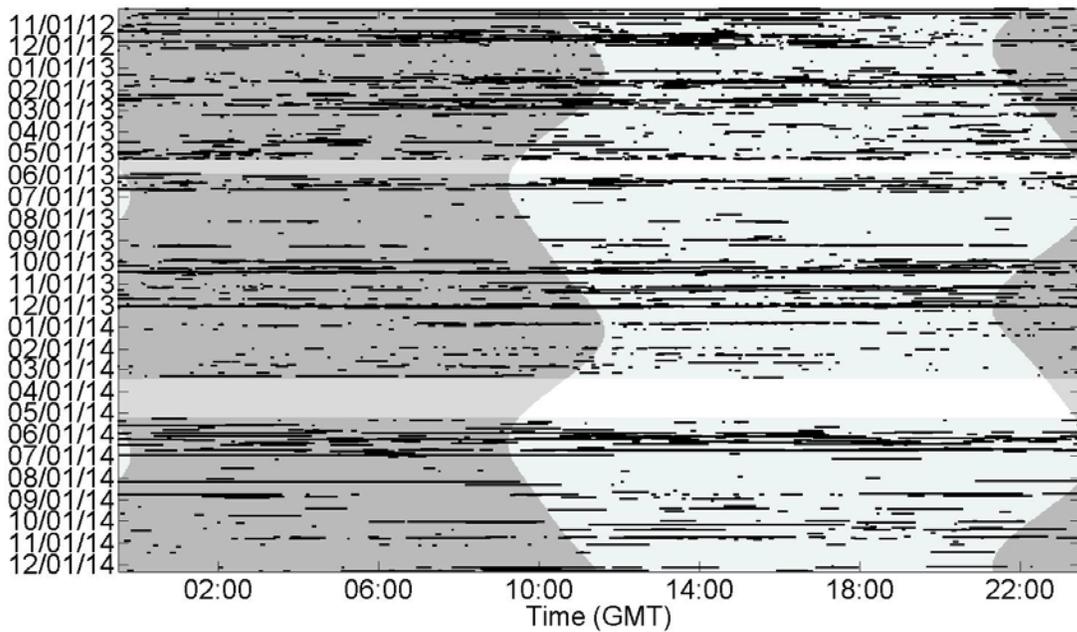

12

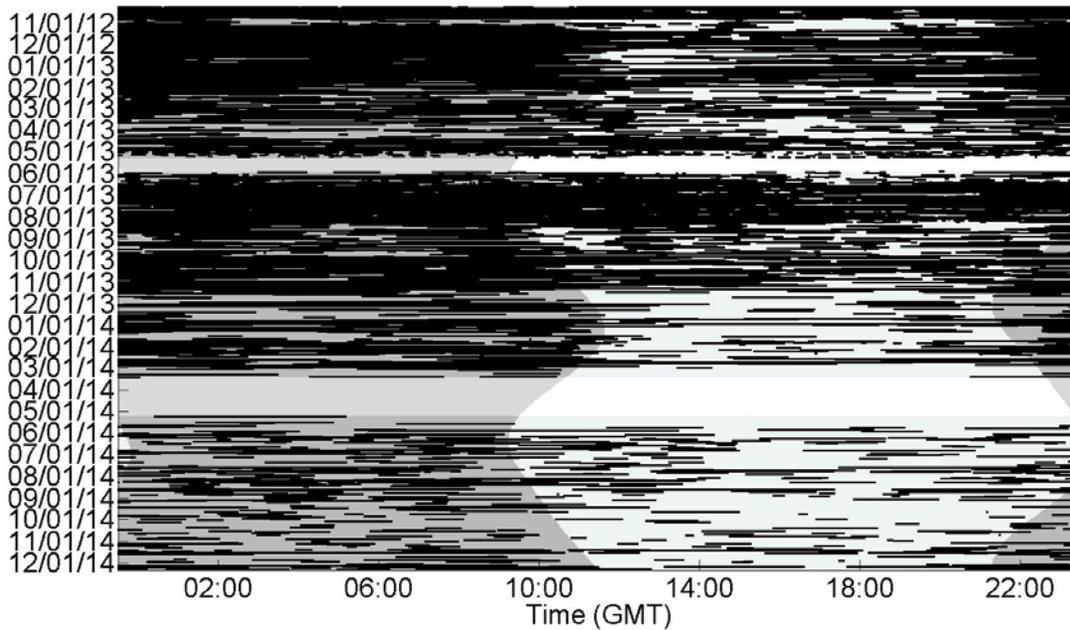

13 **Figure 10. Monthly averages of ambient noise at Cape Hatteras Site A for April 2015–January 2016.**  
14 **Months with an asterisk (\*) are partial recording periods. Peaks in noise around 20 Hz during**  
15 **winter months indicate presence of fin whale calls, and peaks around 120 and 170 Hz are related**  
16 **to the presence of minke whale pulse trains. Increased levels between 12-40 Hz during July and**  
17 **August 2015 indicate the presence of seismic airgun surveys. Figure from Frasier et al. (2017).**

3 **January 2016 Cape Hatteras Site A dataset.**

4

5  
6 **Figure 15. Sei whale downsweeps detections (black bars) in hourly bins within the April 2015–**  
7 **January 2016 Cape Hatteras Site A dataset.**

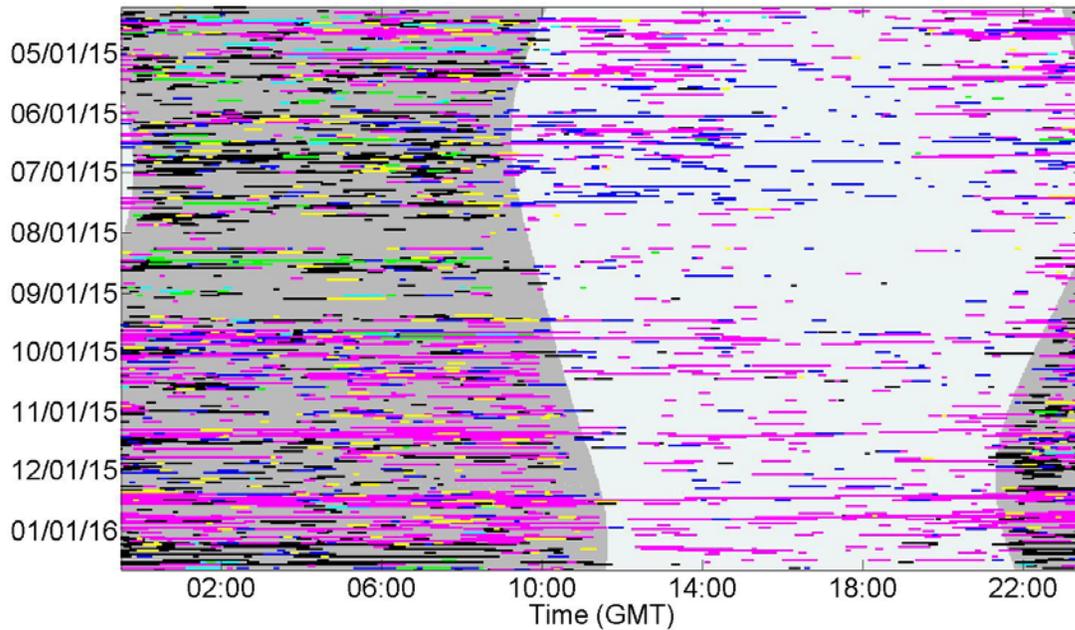

8 Detected odontocete vocalizations were classified as *Kogia* sp. clicks, Risso's dolphin clicks,  
9 sperm whale clicks, Cuvier's beaked whale clicks, Gervais' beaked whale clicks, Blainville's

1 beaked whale (*Mesoplodon densirostris*) clicks, and unidentified odontocete clicks and whistles  
2 (with clicks and whistles analyzed for separately, as discussed in Section 3.3). Many of the  
3 odontocete click detections could not be classified to species but the unclassified clicks were  
4 divided into five main groups based on spectral patterns (**Figure 16**). Altogether, these  
5 unclassified clicks were present nearly continuously throughout each recording period. For more  
6 details on each of the five groups of clicks and which species may have produced them, see  
7 Frasier et al. ([2017](#)). Unidentified odontocete whistles both lower and higher than 5 kHz  
8 occurred very regularly throughout the April 2015–January 2016 dataset, although there were  
9 many more whistles higher than 5 kHz (**Figures 17 and 18**). Clicks produced by *Kogia* sp. were  
10 detected sporadically throughout the deployment (**Figure 19**). Risso’s dolphin clicks were  
11 detected only between May and July (**Figure 20**). Sperm whales were detected throughout the  
12 deployment during both day and night, with peaks in click detections between late July and early  
13 August as well as from late December to the end of recording in January (**Figure 21**). There  
14 were also click detections assigned to three species of beaked whales. Cuvier’s beaked whale  
15 clicks occurred regularly throughout this deployment, with a slight increase in detections  
16 between September and December, as in previous years, as well as between April and May  
17 (**Figure 22**). Gervais’ beaked whale clicks occurred less frequently than Cuvier’s beaked whale  
18 clicks at Cape Hatteras Site A. Most Gervais’ beaked whale detections occurred between April  
19 and July and between November and January (**Figure 23**). Unlike Cuvier’s beaked whales,  
20 there were very few detections of Gervais’ beaked whales between August and October, similar  
21 to previous years. Blainville’s beaked whale clicks were detected only on one day in January  
22 (**Figure 24**).

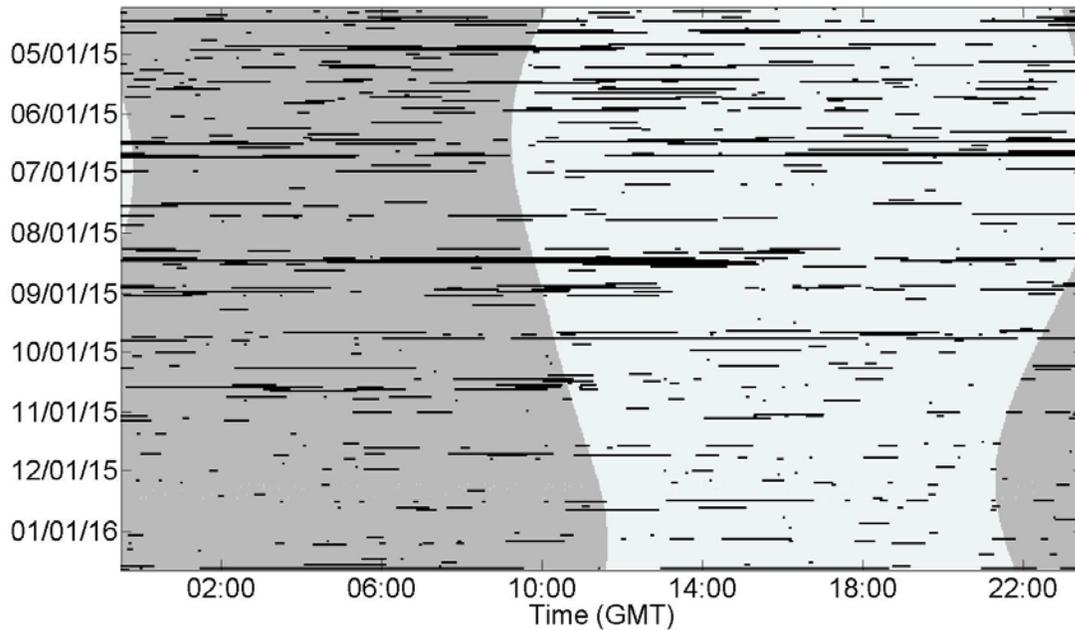

23

24

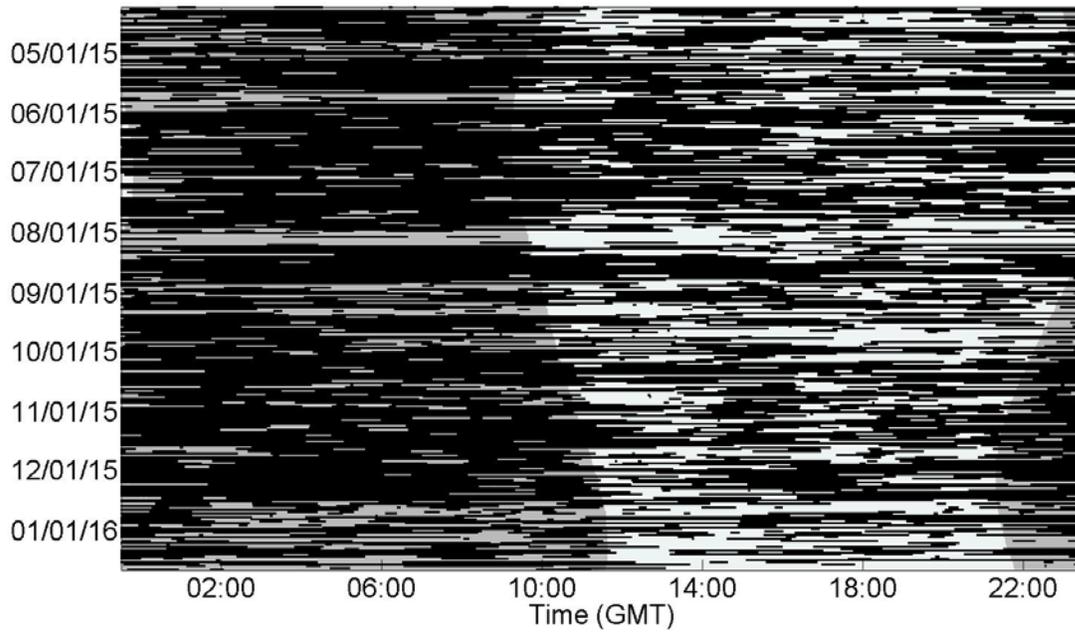

25

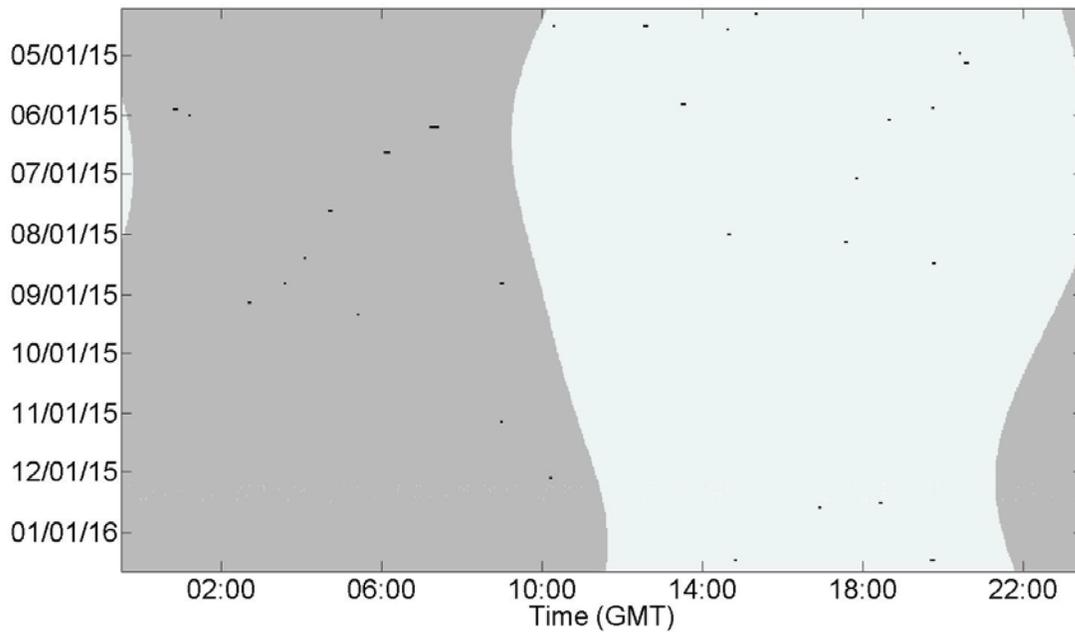

1

4 MFA sonar was detected intermittently throughout the April 2015–January 2016 dataset  
5 recorded at Cape Hatteras Site A, with a peak in detections occurring in October (**Figure 25**).  
6 LFA sonar higher than 500 Hz was detected on one day in September (**Figure 25**). Airguns  
7 were detected throughout the deployment during both day and night, with peaks in detections in  
8 April 2015 and between June and September 2015 (**Figure 26**).

## 6. Jacksonville

### 6.1 Methods

#### Data Collection

The small mooring HARP deployed in 800 m at 30.1489 N, 79.7711 W was recovered on 26 April 2016 (**Table 9; Figure 27**) and redeployed that same day at the same site in approximately 736 m at 30.1518 N, 79.7702 W (**Table 9; Figure 27**). This HARP is still out in the field and is scheduled to be recovered in June 2017. Both HARPs were set to sample continuously at 200 kHz. A schematic diagram of the HARP moorings for the July 2015 and April 2016 deployments can be seen in **Figures 28 through 29**.

**Table 9. Jacksonville, Florida, HARP data sets analyzed and detailed in this report.**

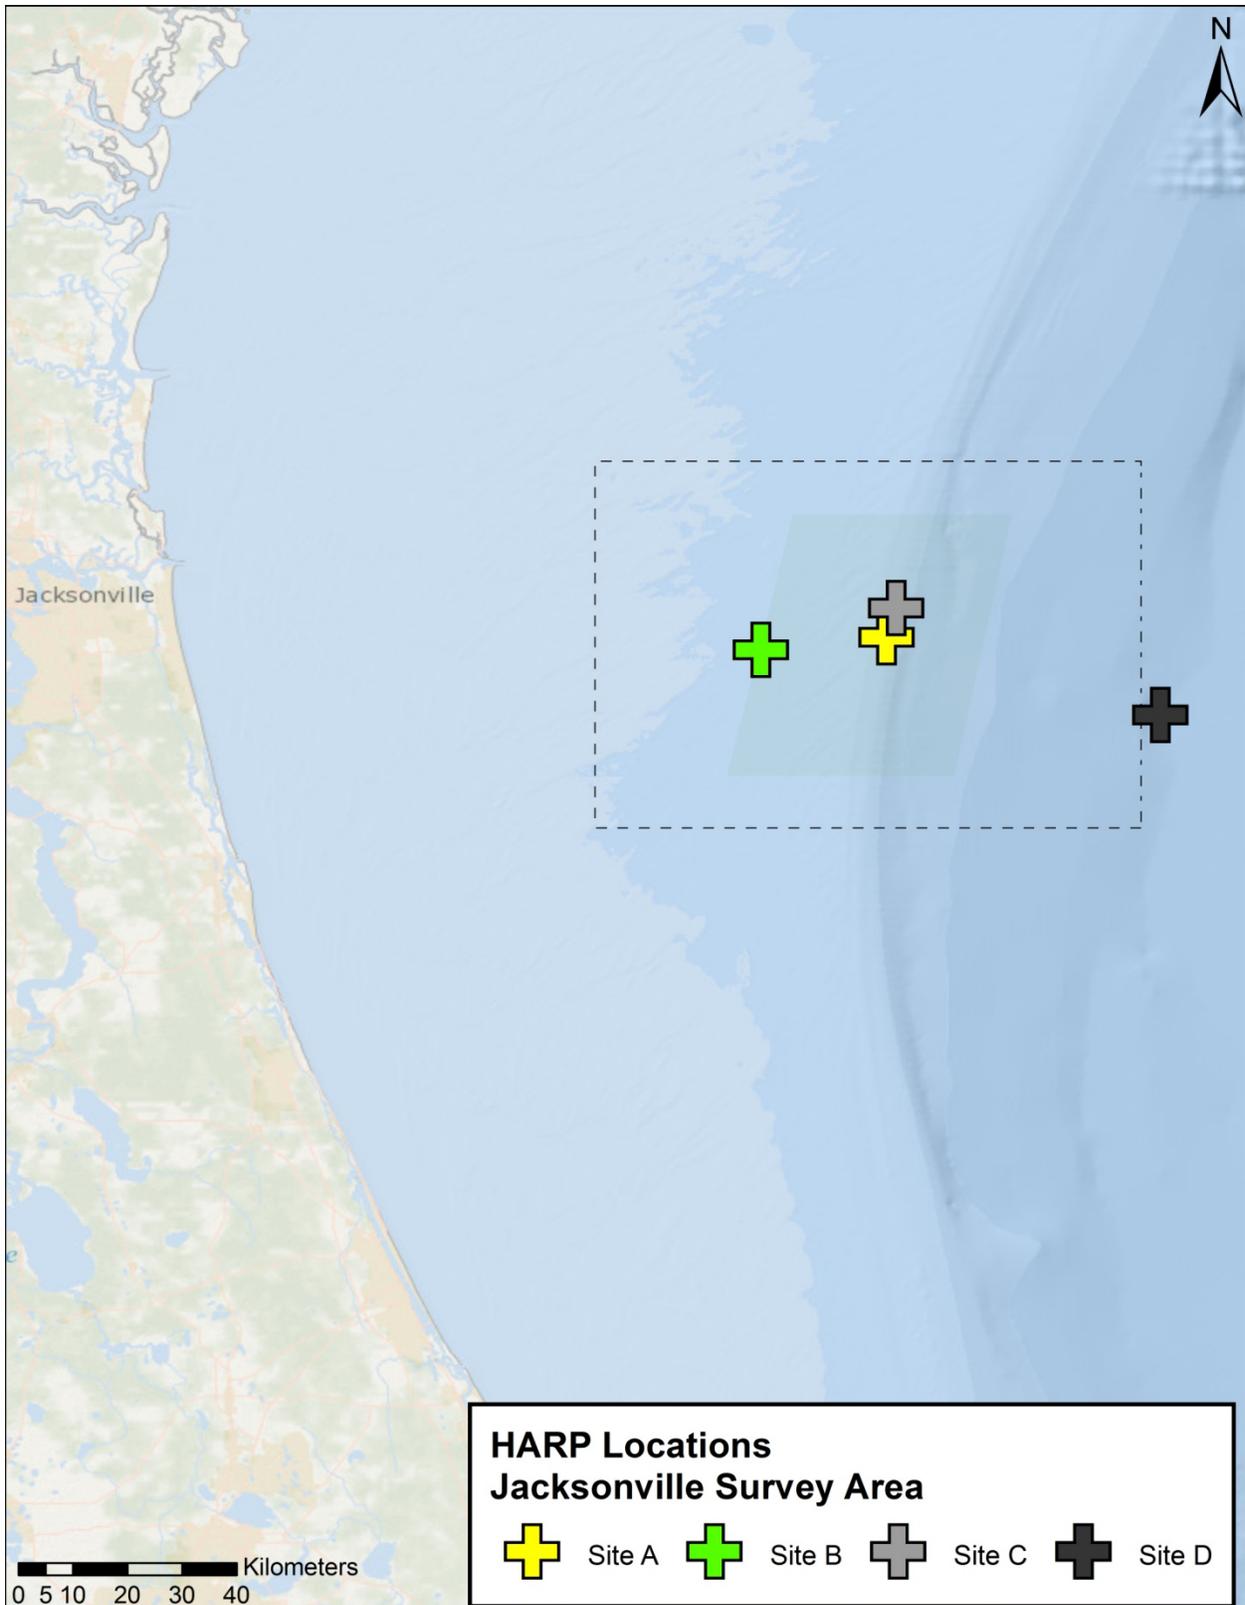

Site	Deployment Date	Retrieval Date	Recording Start Date	Recording End Date	Latitude (N)	Longitude (W)	Depth (m)	Sampling Rate	Duty Cycle
11D	23-Aug-14	2-Jul-15	23-Aug-14	29-May-15	30.1506	79.7701	~806	200 kHz	continuous
12D	2-Jul-15	26-Apr-16	3-Jul-15	4-Nov-15	30.1489	79.7711	800	200 kHz	continuous
13D	26-Apr-16	N/A	26-Apr-16	N/A	30.1518	79.7702	736	200 kHz	continuous

#### Data Analysis

Data from the August 2014 and July 2015 deployments at JAX Site D have been analyzed for marine mammal and anthropogenic sounds and will be reported here as a summary of Frasier et al. (2016) and Varga et al. (2017). The August 2014–July 2015 deployment yielded 6,697 hours of recording time over 280 days, while the July 2015–April 2016 deployment yielded 2,995 hours of recording time over 125 days.

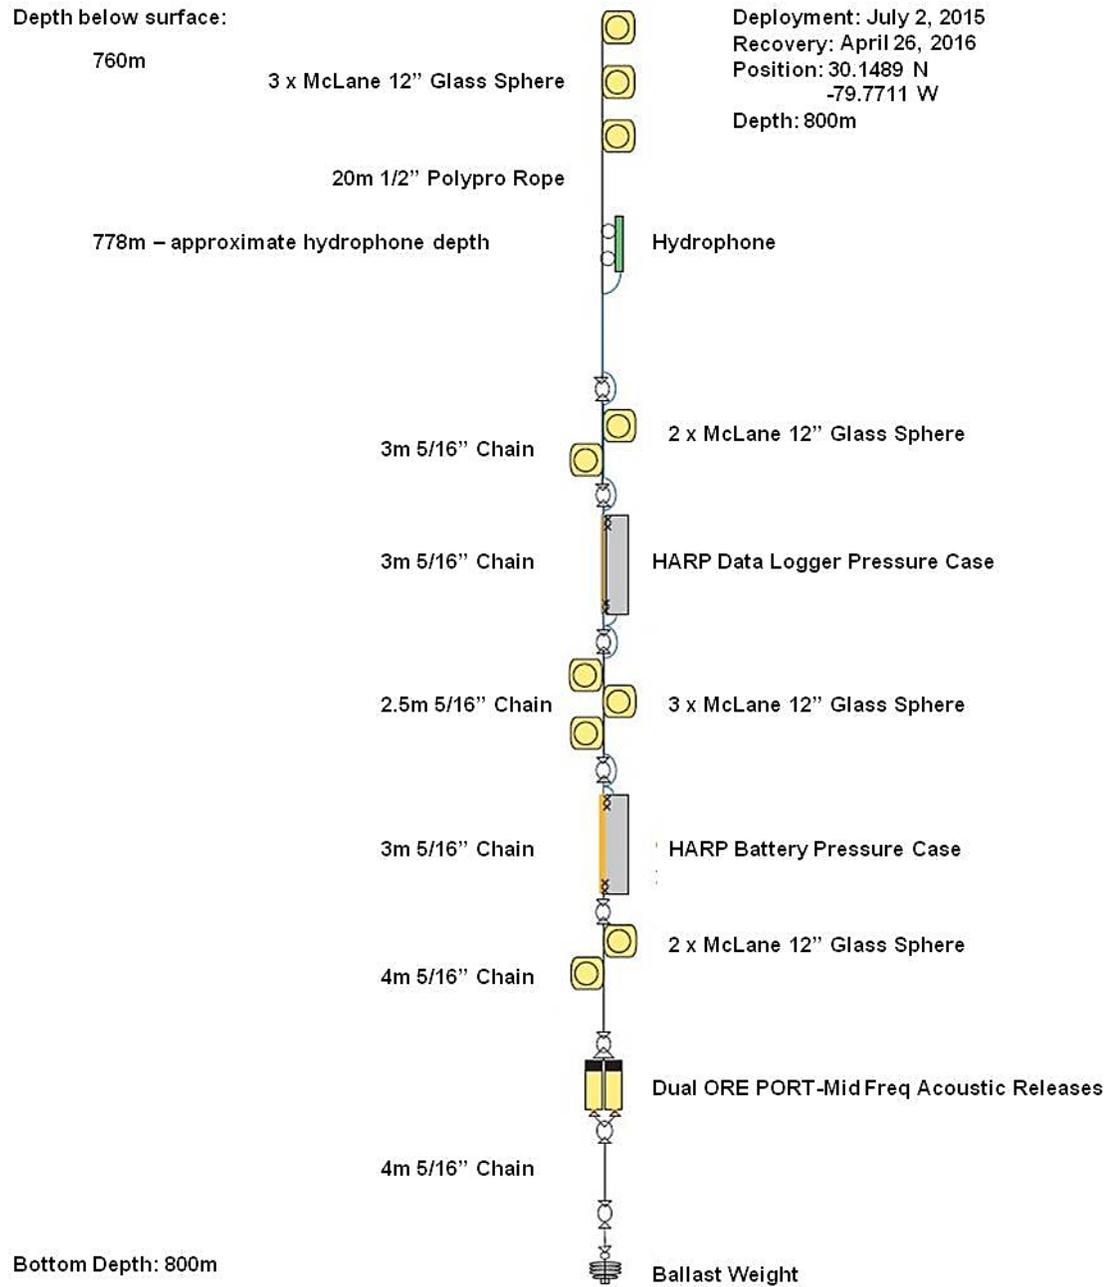

#### Data Quality

Approximately three days after the July 2015 deployment, the LF stage of the hydrophone failed. The majority of the remaining data has little to no sensitivity in the lower frequencies (< ~12 kHz), as well as occasional broadband masking from electronic noise. Despite the failure of the LF component of the hydrophone, it remained sensitive to acoustic signals between ~12 and 100 kHz. For these reasons, the July 2015 dataset could not be analyzed for mysticetes, LFA sonar, MFA sonar, or ships.

## 1 6.2 Results

2 These results are a summary of Frasier et al. (2016) and Varga et al. (2017), with beaked whale  
3 analysis for the August 2014–May 2015 dataset performed by Joy Stanistreet. Monthly  
4 averages of underwater ambient noise during the August 2014–May 2015 JAX Site D dataset  
5 described here is shown in **Figure 30**. Underwater ambient noise could not be measured in the  
6 July–November 2015 dataset because the low frequency data were not usable for reasons  
7 detailed above. **Tables 10 and 11** summarize the detected and identified marine mammal  
8 vocalizations during these two datasets, and **Figures 31 through 42** show the daily occurrence  
9 patterns for the different marine mammal groups (classified to species when possible). **Figures**  
10 **43 and 44** show the occurrence of MFA sonar and HFA sonar, respectively.

11  
12 **Figure 30. Monthly averages of ambient noise at JAX Site D for August 2014–May 2015. Months**  
13 **with an asterisk (\*) are partial recording periods. Increased levels between**  
14 **December and March are from the presence of minke whale pulse trains. Figure from Frasier et al.**  
15 **(2016).**

16 Only the August 2014–May 2015 dataset could be inspected for mysticete calls due to the  
17 equipment failure described in Section 4.1. In the August 2014–May 2015 dataset, calls from fin  
18 whales, minke whales, and sei whales were detected. Fin whale 20-Hz pulses were detected  
19 between January and March 2015 (**Figure 31**). Minke whale pulse trains were detected first in  
20 October 2014, with detections ramping up to almost continuous (on an hourly basis) in  
21 December and remaining at elevated levels through March 2015 (**Figure 32**). Minke whale  
22 pulse trains started decreasing in April and were not detected after early May 2015 (**Figure 32**).

- 1 Sei whale downsweeps were detected between November 2014 and January 2015, with a peak
- 2 in detections in January (**Figure 33**).

1 **Table 10. Summary of detections of marine mammal vocalizations at JAX Site D for August 2014–**  
 2 **May 2015.**

Species	Call Type	Total Duration of Vocalizations (hours)	Percent of Recording Duration	Days with Vocalizations	Percent of Total Recording Days
Fin whale <sup>a</sup>	20 Hz	76	1.1	13	4.6
Minke whale <sup>a</sup>	pulse train (slow-down, speed-up, regular)	3654	54.6	184	65.7
Sei whale <sup>a</sup>	downsweep	88	1.3	17	6.1
Unidentified odontocete <sup>b</sup>	clicks	382.2	5.7	218	77.9
Unidentified odontocete <sup>c</sup>	whistles	423.3	6.3	181	64.6
<i>Kogia</i> sp. <sup>c</sup>	clicks	10.5	0.2	80	28.6
Risso's dolphin <sup>b</sup>	clicks	93.3	1.4	131	46.8
Sperm whale <sup>c</sup>	clicks	28.6	0.4	11	3.9
Blainville's beaked whale <sup>b</sup>	clicks	0.7	0.01	2	0.7
Gervais' beaked whale <sup>b</sup>	clicks	2.2	0.03	4	1.4

<sup>a</sup> Analyzed in hourly bins.

<sup>b</sup> Analyzed in 5-minute bins.

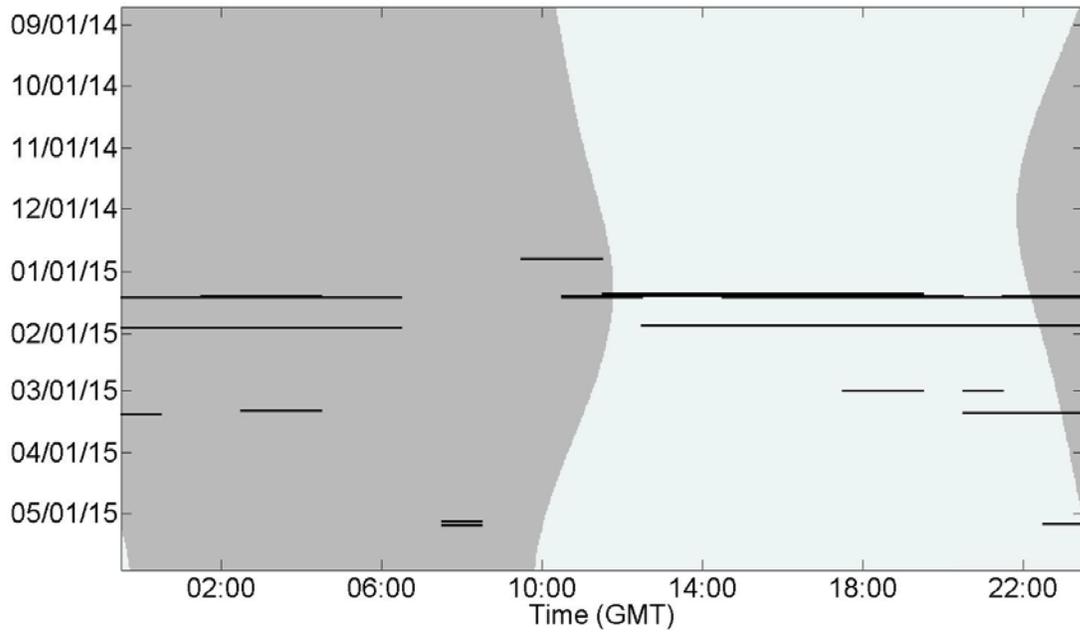

<sup>c</sup> Analyzed in 1-minute bins.

3 **Table 11. Summary of detections of marine mammal vocalizations at JAX Site D for July–**  
 4 **November 2015. Note that detections of unidentified odontocete whistles less than 5 kHz were**  
 5 **likely missed due to the hydrophone failure mentioned previously.**

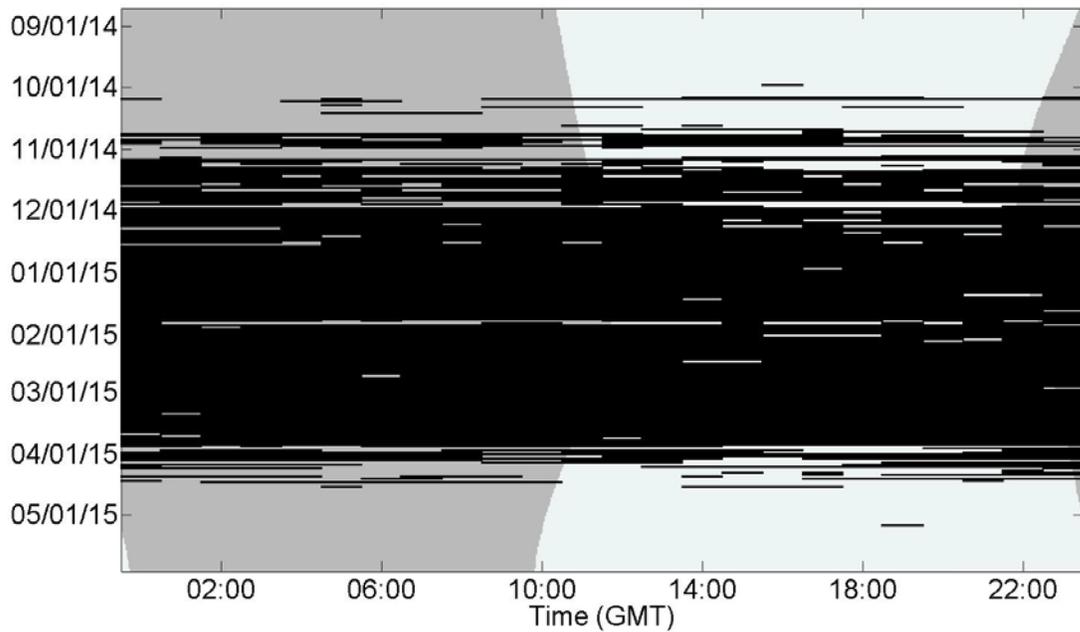

Species	Call Type	Total Duration of Vocalizations (hours)	Percent of Recording Duration	Days with Vocalizations	Percent of Total Recording Days
Unidentified odontocete <sup>a</sup>	clicks	73.70	2.46	87	69.6
Unidentified odontocete <sup>b</sup>	whistles	23.92	0.80	33	26.4
<i>Kogia</i> sp. <sup>b</sup>	clicks	14.92	0.15	100	80
Risso's dolphin <sup>a</sup>	clicks	144.75	1.49	180	144
Sperm whale <sup>b</sup>	clicks	79.78	0.82	23	18.4
Blainville's beaked whale <sup>a</sup>	clicks	0.68	0.007	2	1.6
Cuvier's beaked whale <sup>a</sup>	clicks	0.48	0.005	3	2.4
Gervais' beaked whale <sup>a</sup>	clicks	3.58	0.04	8	6.4

<sup>a</sup> Analyzed in 5-minute bins.

5 **Figure 32. Minke whale pulse train detections (black bars) in hourly bins within the August 2014–**  
6 **May 2015 JAX Site D dataset.**

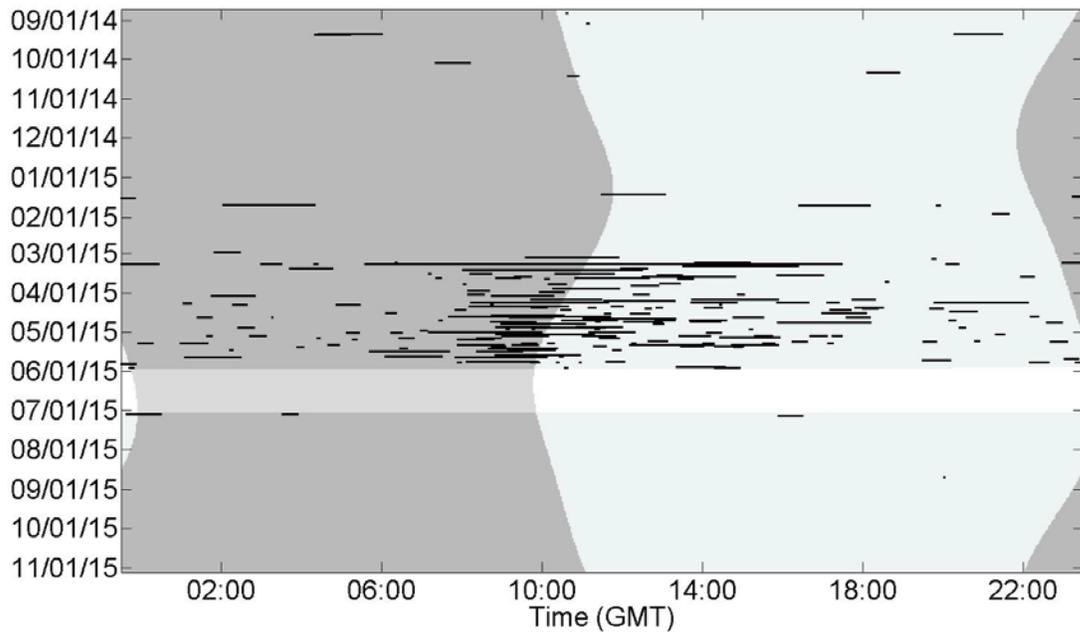

1

2 **Figure 33. Sei whale downsweep detections (black bars) in hourly bins within the August 2014–**  
3 **May 2015 JAX Site D dataset.**

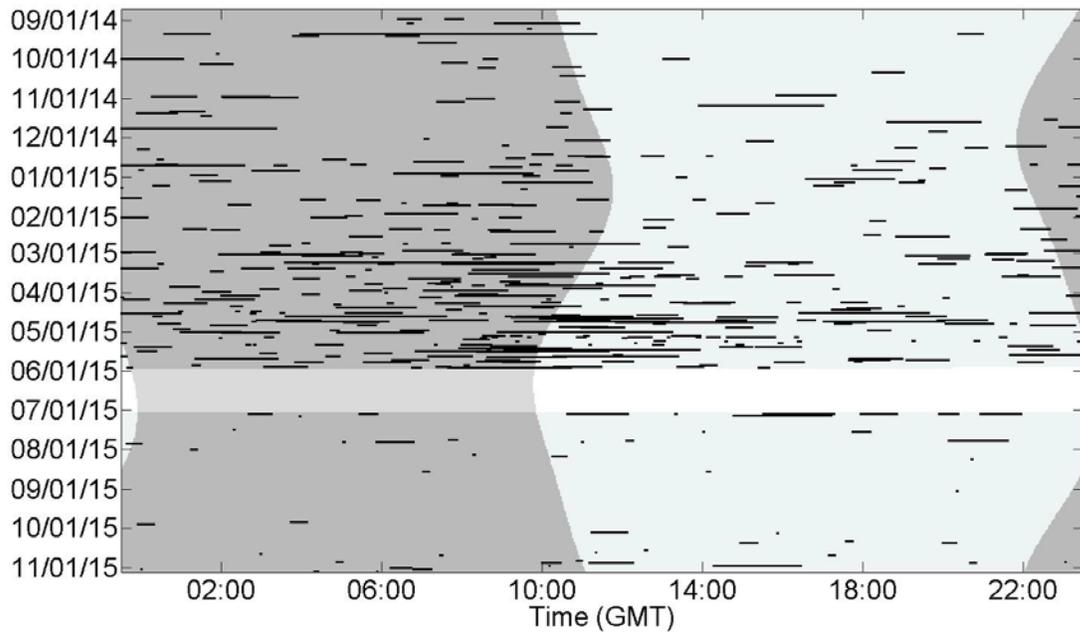

4 Detected odontocete vocalizations included clicks and whistles (**Figures 34 through 42**). Most  
5 of these detections were assigned to the unidentified odontocete category (**Figure 34**), with  
6 clicks being divided into three main groups based on spectral patterns in the August 2014–May  
7 2015 dataset and into two main groups based on spectral patterns in the July–November 2015  
8 dataset (see Frasier et al. [2016] and Varga et al. [2017] for more details). Unidentified  
9 odontocete whistles lower than 5 kHz were detected mainly between March and May 2015 in  
10 the August 2014–May 2015 dataset, mainly during late night and early morning hours (**Figure**  
11 **35**). There were not many detections of unidentified whistles lower than 5 kHz during the July–  
12 November 2015 dataset (**Figure 35**), but that is likely due to the hydrophone failure mentioned  
13 previously which undoubtedly resulted in many missed detections. Unidentified odontocete  
14 whistles higher than 5 kHz were detected throughout both datasets, with peaks in detections  
15 between March and May 2015 (**Figure 36**). Once again, though, there were possibly missed  
16 detections in this category during the July–November 2015 dataset if the whistles did not extend  
17 above 12 kHz. *Kogia* clicks were detected throughout both datasets examined here, with  
18 highest numbers of detections occurring between October 2014 and April 2015 (**Figure 37**).  
19 Risso’s dolphins were detected in low numbers between August 2014 and April 2015 and in  
20 higher numbers in late April through May 2015 and in July 2015, with detections primarily at  
21 night (**Figure 38**). Sperm whales were detected intermittently throughout both deployments  
22 (**Figure 39**). Blainville’s beaked whales were detected on only two days during the August  
23 2014–May 2015 dataset and never during the July–November 2015 dataset (**Figure 40**).  
24 Conversely, Cuvier’s beaked whale clicks were not detected during the August 2014–May 2015  
25 dataset and detected on only three days during the July–November 2015 dataset (**Figure 41**).  
26 Gervais’ beaked whales were detected on four days during the August 2014–May 2015 dataset  
27 and three days during the July–November 2015 dataset (**Figure 42**). Most beaked whale  
28 detections during these deployments occurred at night (**Figures 40 through 42**).

6 **Figure 41. Cuvier's beaked whale click detections (black bars) in one-minute bins within the**  
7 **August 2014–May 2015 and July–November 2015 JAX Site D datasets. Note there were no**  
8 **detections in the August 2014–May 2015 dataset.**

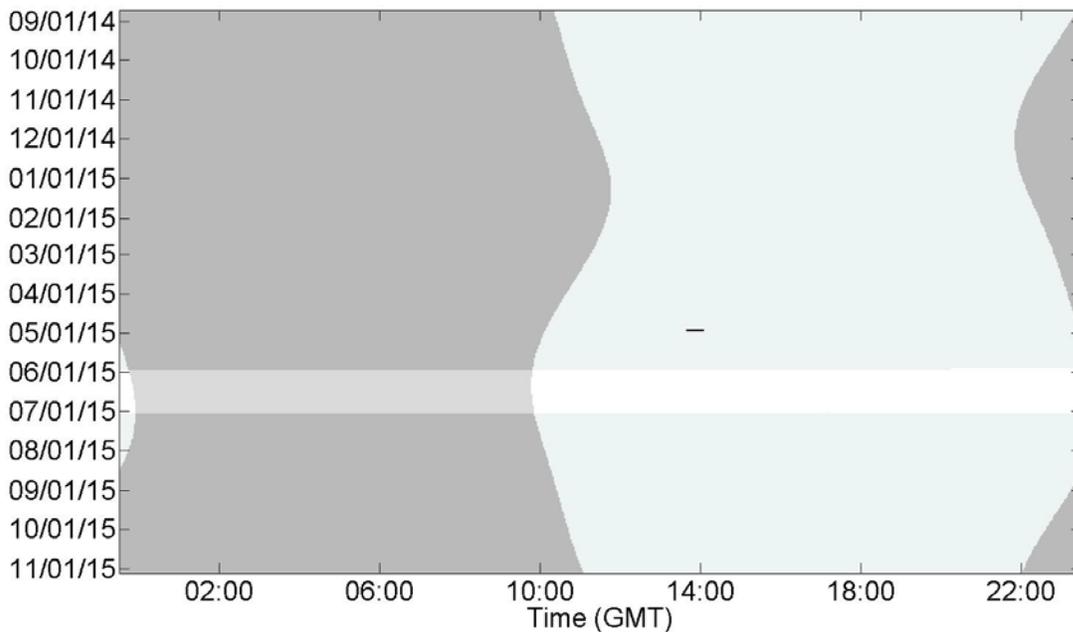

1  
2 **Figure 42. Gervais' beaked whale click detections (black bars) in 1-minute bins within the August**  
3 **2014–May 2015 and July–November 2015 JAX Site D datasets.**  
4 MFA sonar was detected in almost every month during the August 2014–May 2015 dataset,  
5 with a peak in detections occurring in September 2014 and January 2015 (**Figure 43**). MFA  
6 sonar could not be analyzed in the July–November 2015 JAX Site D dataset due to the  
7 hydrophone failure mentioned previously. HFA sonar was detected on one day during the  
8 August 2014–May 2015 dataset (**Figure 44**).

7 **detections in the July–November 2015 dataset.**

## 1 7. Current and Anticipated Analyses for 2017

- 2 Scripps Institution of Oceanography will analyze the April 2016 datasets from Norfolk Canyon
- 3 Site A, Cape Hatteras Site A, and Jacksonville Site D once they are recovered in June 2017.
- 4 Detailed and technical reports will be available once the analyses of the datasets are complete.

## 1 8. Acknowledgements

2 We would like to thank U.S. Fleet Forces Command and Joel Bell (Naval Facilities Engineering  
3 Command Atlantic) for providing support for this project. We thank Tim Boynton, Zach Swaim,  
4 Ryan Griswold, John Hurwitz, and Stormy Harrington and crew of the *Tiki XIV* for help with  
5 HARP preparation, deployments, and retrievals. We thank Sean Wiggins and Bruce Thayre for  
6 help in removing glitches in the Hatteras datasets. We thank Simone Baumann-Pickering for  
7 help with the beaked whale code. Jennifer Dunn provided administrative support, and Heather  
8 Foley created the maps in this report.
