13. SUPPLEMENTARY NOTES

14. ABSTRACT
Scientific diving teams surveyed the benthic community in the turning basin and surrounding shoals in Apra Harbor, Guam to support analysis of potential impacts from constructing a proposed large vessel wharf in the Outer Harbor. A total of 72 locations were surveyed. Bottom substrates ranged from a nearly 100% cover of living coral structures to fine silty/sand-covered bottom. The sites included high percent cover of coral communities dominated by a *Porites rus* and *Porites horizontalata* complex, mixed coral communities with higher diversity coral and sponge assemblages, areas of relatively dense macroalgae, depauperate silty-sand bottom areas, and various combinations of these habitats.

15. SUBJECT TERMS
benthic cover; coral colony size; coral density; rugosity; quadrats, belt transect, in-situ measurement

This work product represents the final deliverable for Task 1 under Contract No. N62470-10-3011-CTO KB03. It documents methodology, summary data, field observations, and photo-logs from benthic community surveys conducted in the CVN Project Area. The included CD contains raw data from the field surveys, which are presented in a flat-file format as Excel spreadsheets.

1.0 INTRODUCTION

A portion of U.S. Marine Corps (Marine Corps) forces currently located in Okinawa, Japan, is planned to be relocated to Guam as a result of redefining the United States (U.S.) defense posture in the Pacific region and the U.S. alliance with Japan. One component of this planned move is the provision to provide safe access and new temporary berthing facilities for nuclear aircraft carriers (CVN) in Apra Harbor, Territory of Guam.

To enable the carriers to safely access Apra Harbor, selected areas of the entrance channel and turning basin in the southeastern part of the harbor, as well as areas chosen for berthing, must be dredged to a depth of 51.5 ft below mean lower low water (MLLW) (DON, 2010). Although much of this area was previously dredged in 1946 to create the existing navigation channel in the harbor, it is projected that additional dredging will be required to accommodate the CVN. If such dredging were to occur, it would directly impact existing benthic marine communities, including coral reefs, within the proposed dredge footprint. Benthic communities in areas adjacent to the dredge footprint also may be indirectly impacted due to the dredging operations. The direct and indirect impact areas together make up the CVN project area (**Figure 1**).

The objective of Task 1 was to survey and characterize the existing benthic and coral reef community within the footprint of the CVN project area. A total of 72 locations were surveyed for 11 parameters (**Table 1**). Task 1 survey data will be used to augment data from prior benthic surveys conducted in Apra Harbor by the Department of the Navy. All benthic and coral reef data collected from within Apra Harbor will be evaluated for input into a Compensatory Mitigation Plan needed for Clean Water Act Section 404 and River and Harbors Act Permits.

Table 1. Benthic and Coral Reef Community Survey Parameters

Parameter	Variable	Metric
1	Algae abundance by species (or lowest possible taxonomic level)	Percent of bottom covered
2	Coral colony abundance: density of colonies by species (or lowest possible taxonomic level) and morphological form	Number of colonies/m ²
3	Coral colony size	Length of longest axis in centimeters
4	Coral fragments	Number and size
5	Partial coral colony mortality	Percent mortality on colonies with complete fission
6	Occurrence of gross growth anomalies or anomalous patterns of tissue loss by species (or lowest possible taxonomic level)	Percent of colonies showing the described condition
7	Mobile macro-invertebrate density by species (or lowest possible taxonomic level)	Number of individuals/m ²
8	Sessile macro-invertebrate (especially sponges) abundance by species (or lowest possible taxonomic level)	Percent of bottom covered or other relevant measure (e.g., for sponges)
9	Occurrence of protected species (e.g., sea turtles)	Presence-absence/site
10	Rugosity	Rugosity index
11	Benthic cover	Percent cover of coral, algae, sand, sponge

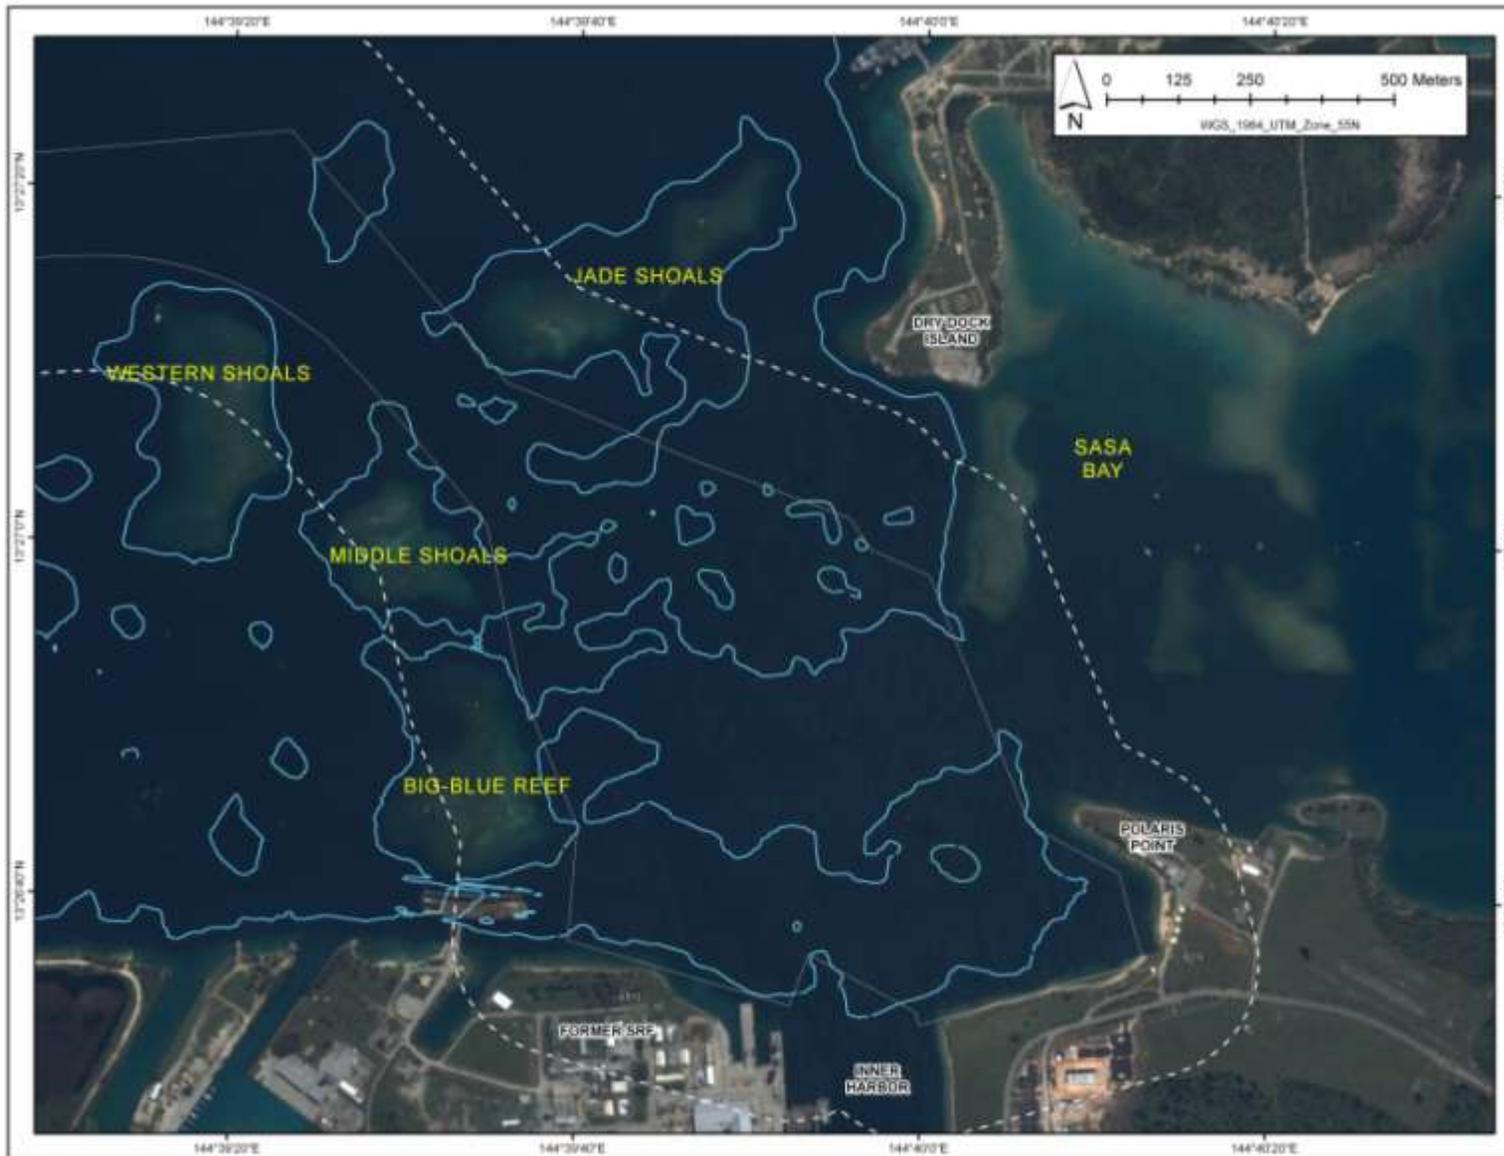

Figure 1. CVN Project Area

2.0 SELECTION OF SURVEY SITES

In April and May 2009, Dollar et al. (2009) evaluated benthic community composition at 67 sites within the CVN project area using the photo-quadrat belt transect (PQBT) method (**Figure 2** and **Table 2**). **Figure 2** shows the sites surveyed by Dollar et al., with individual sites falling within the then-anticipated areas of either direct impacts (bounded by solid line) or indirect impacts (bounded by dashed line) resulting from the dredging project. The 67 sites surveyed during this study were located in relatively shallow waters (≤ 60 ft deep) and were separated into the following four “strata:”

- Direct Flat – within proposed dredging footprint and $\leq 15^\circ$ incline;
- Direct Slope - within proposed dredging footprint and $> 15^\circ$ incline;
- Indirect Flat – adjacent to proposed dredging footprint and $\leq 15^\circ$ incline; and
- Indirect Slope - adjacent to proposed dredging footprint and $> 15^\circ$ incline.

The efficacy of the PQBT method for determining benthic community composition was compared to that of the *in-situ* quadrat (ISQ) method by another study conducted concurrently by the US Fish and Wildlife Service (USFWS), the Guam Coastal Management Program, and NOAA’s National Marine Fisheries Service (NMFS)¹ (Minton et al., 2009) with the Dollar et al. survey. During this study, comparative data were collected for all parameters shown in **Table 1** at 30 of the 67 transects surveyed by Dollar et al. (2009) (**Figure 2**). These sites are identified by the green colored text in both **Table 2** and **Figure 2**. This study concluded that the most likely preferred option for characterization of the benthic community within the CVN project area, including coral reefs, was a combination of ISQ and PQBT methods.

Task 1 surveys included the remaining 37 sites that were not surveyed by Minton et al. and an additional 35 new sites, for a total of 72 sites. All 72 sites were surveyed using a combination of ISQ and PQBT methods (further described in **Section 3**) for the parameters listed in **Table 1**.

2.1 Identification of the 35 New Survey Sites

Initial guidance from the Navy received prior to the start of the field work had indicated that locations for the 35 new sites to be surveyed under Task 1 would be provided by the Resource Agencies (RA). Guidance received from the RAs, however, only contained general recommendations to be followed for selecting the additional survey sites. The Navy then redirected the survey team to identify locations for the new survey sites based on the best available science and data while ensuring that RAs’ recommendations were also considered.

Identification of the 35 new survey sites was accordingly based on the premise that coral abundance and site homogeneity/heterogeneity were likely to vary among the various strata in Apra Harbor and that more corals typically reside at shallower depths compared to deeper locations.

¹ The three agencies are collectively referred to as the Resource Agencies (RA).

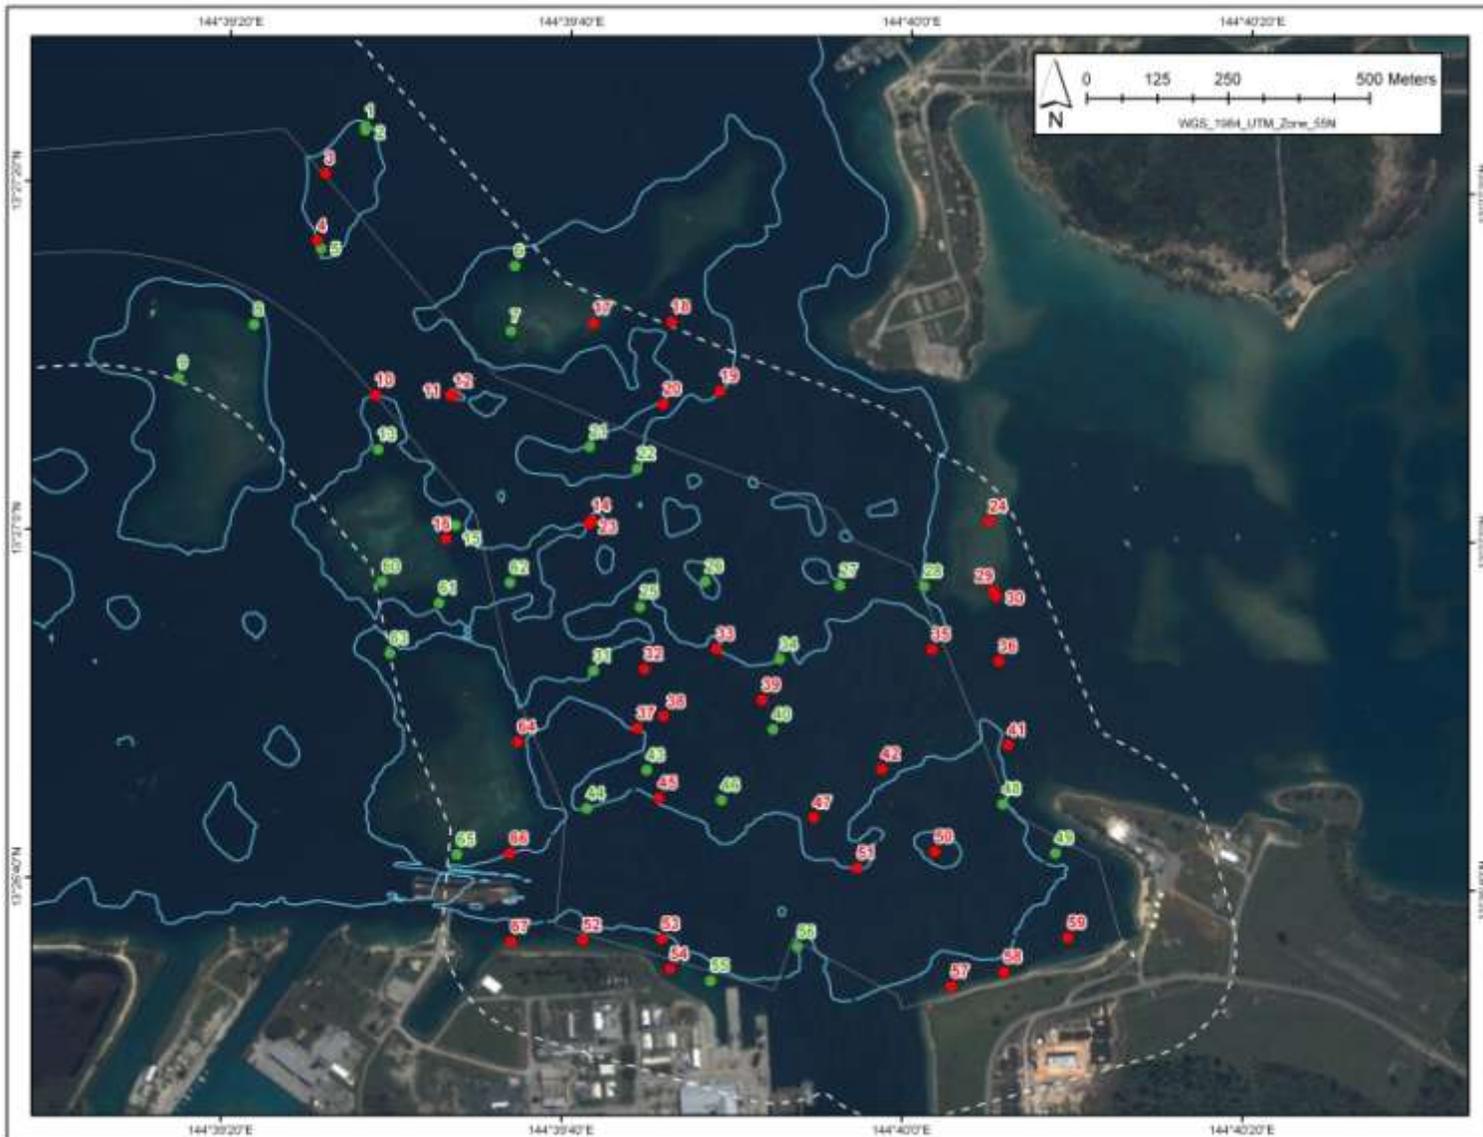

Figure 2. Locations of the 67 Sites Surveyed by Dollar et al. in 2009 (30 of the 67 sites surveyed by Minton et al. (2009) are shown in green)

Notes:

1. All sixty-seven (67) sites were surveyed by Dollar et al. in 2009 using the photographic quadrat method.
2. Thirty (30) of the Dollar et al. sites (geographic coordinates shown in **BOLD** and **GREEN**) were surveyed by Minton et al. in 2009. Comparative surveys were conducted using photographic quadrat and *in-situ* quadrat methods.
3. The remaining 37 Dollar et al. sites (geographic coordinates shown in *ITALICS* and *RED*) were surveyed under Task 1 in 2010 using the *in-situ* quadrat method.

The process also considered the RA recommendation that the new sites cover the following six strata:

- Shallow reef flats (SRF)
- Deep reef flats (DRF)
- Windward shallow reef slopes (WSS)
- Leeward shallow reef slopes (LSS)
- Deep slopes (DS)
- Northernmost pinnacles (NMP)

A three-step process was followed to optimize the survey design and distribute the 35 new sites between the six strata recommended by the RAs.

- Step 1 – Determine the optimum number of sites to be surveyed in shallow (≤ 60 ft) vs. deeper (> 60 ft) areas.
- Step 2 – From Step 1, take the optimum number of survey sites determined for shallow areas and distribute them among reef flats, windward slopes, leeward slopes, and northernmost pinnacles that occur at depths of ≤ 60 ft.
- Step 3 – From Step 1, take the optimum number of survey sites determined for deeper areas and distribute them among reef flats, windward slopes, leeward slopes, and northernmost pinnacles that occur at depths of > 60 ft.

To determine a statistically valid number of shallow and deep water sites, a prospective power analysis (SAS – ProcGOMPow) was conducted using summary data from the Dollar et al. study. A power analysis reports the power of a means comparison test (e.g., ANOVA) given a proposed study sample size, significance level, response and classification variables, expected means and sample standard deviations.

Statistical power is the probability of successfully rejecting the null hypothesis (H_0), i.e. not accepting the H_0 when it is false. In this case the H_0 was that there was *no difference* in mean coral abundance, or mean species richness, between the two given strata, namely shallow and deep. The test hypothesis (H_1) was that there *were* differences between strata.

A power level of 0.80 for example, for a given distribution of survey sites between shallow and deeper waters (say 2:1 ratio), would indicate that there is an 80% probability that the test would accurately detect differences between the two depths when the difference actually exists. In other words, if the survey sites were distributed between shallow and deeper waters in a 2:1 ratio, a power level of 0.80 for this distribution ratio would mean that there is at least an 80% chance of successfully rejecting H_0 (survey design *would not be able to detect differences* in mean coral abundance or mean species richness between the two depths that are actually different) and

accepting H_1 (survey design *would be able to detect* differences in mean coral abundance or mean species richness between the two depths that are actually different).

A detailed description of the analyses is presented in **Appendix A**. Key steps are summarized below:

- Dollar et al. (2009) had previously reported point counts as a measure of coral abundance at 67 transects.
- Using summary data contained in the Dollar et al. (2009) and Minton et al. (2009) reports mean point counts were estimated for each of the four strata represented by the 67 transects, namely direct flat, direct slope, indirect flat, and indirect slope.
- Mean point counts between direct flat and direct slope were very similar (106.95 and 101.17, respectively), indicating that coral abundance between these two strata, at least as measured by mean point counts, was not radically different.
- Mean point counts between indirect flat and indirect slope however differed considerably (186.08 and 278.07, respectively) and were therefore judged suitable for use in distinguishing between the two strata using tests such as a GLM POWER procedure. It was assumed that the indirect flat and indirect slope point count data sets were normally distributed.
- The four strata then were transposed into the six strata recommended by the RA using the following criteria:
 - SRF and DRF = Flat ($\leq 15^\circ$)
 - WSS, LSS, DS, and NMP = Slope ($> 15^\circ$)
- For each of these six strata, mean point counts were estimated based on extrapolation of data from the Dollar et al. study (**Table 3**).
- To determine the optimum distribution of the Task 1 survey effort among shallow and deep sampling locations, various weights were assigned to shallow vs. deep strata, with the understanding that shallow strata will be more likely to contain corals. A 2:1 shallow-to-deep weighting ratio was considered reasonable based on prior knowledge of coral occurrence at various depths. This ratio resulted in a high probability that differences in coral distribution would be detected based on this distribution, yielding a power of 0.77 to 0.822 for species richness, and 0.955 for mean point count.
- Since the 67 sites surveyed by Dollar *et. al.* were located at ≤ 60 ft depth, it was evident that additional deep water sites (> 60 ft depth) were needed to provide representative coverage of the harbor. Also, the RAs had recommended that not all of the 35 new sites be located in deeper areas and the power analyses had indicated a 2:1 ratio of shallow (≤ 60 ft) vs. deep (> 60 ft) sites would ensure a high probability that differences in coral distribution would be detected between the depths.
- Accordingly, 20 of the 35 new sites were placed at depths ranging from 60 to 90 ft and the remaining 15 were located in shallower water (8 at depths of ≤ 30 ft and 7 at depths ranging from > 30 to 60 ft) (**Table 4**).
- Collectively, the pool of 72 sites surveyed under Task 1 included 48 shallow (< 60 ft) and 24 deep (≥ 60 ft) sites, a 2:1 ratio between the two depth ranges.

Table 3. Six Strata with Mean Species Richness and Mean Point Counts

Strata	Estimated Mean Point Count*
Shallow reef flats (SRF)	186.08
Deep reef flats (DRF)	186.08
Windward shallow reef slopes (WSS)	278.07
Leeward shallow reef slopes (LSS)	278.07
Deep slopes (DS)	278.07
Northernmost pinnacles (NMP)	278.07

*Extrapolated from Dollar et al., 2009

Table 4. Task 1 New Survey Transect Stratification

Strata	Location	Habitat Characteristics	Depth Range (ft)	Number of Sites	Individual Site No.'s
Shallow reef flats	Located along the crests of Jade Shoal, Western Shoal, Middle Shoal, and Big Blue Reef	Typically comprising areas of mixed stony corals (primarily <i>Porites lutea</i> and other massive <i>Porites</i> species, <i>Porites cylindrica</i> , and <i>Porites rus</i>) along with macroalgae, sponges, sand, and coral rubble	4 to 7	4	69, 83, 93, 98
Outboard (higher-energy) shallow reef slopes	Located along the western margins of Jade Shoal, Western Shoal, Middle Shoal, Big Blue Reef, and the shoal between the CVN project area and Sasa Bay to the east	Predominantly high in living coral cover, with a macroalgal component at several locations: western-facing and leeward relative to predominant wind direction	20 to 39	5	70, 71, 84, 91, 99
Inboard (lower-energy) shallow reef slopes	Located along the more eastern-facing margins of Western Shoal and Big Blue Reef, and along the shoal on the eastern side of the harbor	Lower coral cover with macroalgae and rubble: generally more eastern-facing and windward relative to predominant wind direction	22 to 40	3	73, 76, 85
Deep reef flats	Within northern section of turning basin	Macroalgae on silt-covered rubble bottom (generally areas that had been previously dredged)	48	1	74
Deep slope	At >50 ft depths along edges of deep reef flats and large reef mounds throughout project area	Slopes with silt-covered rubble, corals, macroalgae, sponges	51 to 90	14	68, 72, 80, 86, 87, 89, 90, 94, 95, 96, 97, 100, 101, 102
Pinnacles	Within northern section of turning basin	Deeper slopes of smaller diameter pinnacle features with silt-covered rubble, macroalgae, sponges, corals	65 to 89	8	75, 77, 78, 79, 81, 82, 88, 92

To ensure that the Task 1 survey design also adequately captured other aspects of the RA recommended stratification (besides depth), data from Dollar *et al.* and Minton *et al.* were evaluated and the new sites were distributed among the various strata as described in **Table 4**. These additional strata included a combination of water depth, slope, and orientation to wind direction, or predominant wave/swell direction, which is more critical in a semi-enclosed harbor.

The terms “windward” and “leeward” were used by the RA to differentiate between shallow reef slope habitat directional orientations. Although synonymous with predominant wave and swell direction when discussing reefs surrounding an island, these terms can become somewhat problematic when used in the context of a semi-enclosed water body, such as Apra Harbor. This is due to the predominant wind direction from the east, which by definition makes the east sides of the harbor reefs windward and would expose them to persistent wave and swell action if they were situated outside of the harbor. However, the project area is located in the southeastern section of Apra Harbor and winds from the east have limited fetch and only rarely create moderate size waves, while the harbor entrance to the west allows ocean swells to enter from this direction and break across the western faces of the shallow reefs on a regular basis. Because of this the leeward sides of the harbor reefs are more influenced by wave and swell action, while the windward reef faces may be slightly more impacted by elevated levels of sediments in the water column caused by stronger afternoon winds from the east.

Thus, to more clearly explain reef orientation within the harbor, the term “outboard” is used in this report to define shallow reef slopes facing from approximately south-southwest to north-northwest. These outboard reef slopes are generally impacted by larger waves and swells from the mouth of the harbor and can therefore also be considered as being relatively “higher-energy.” Correspondingly, the term “inboard” (lower-energy) is used for reef slopes that were oriented more toward the east or were sheltered from larger waves/swells because they are oriented away from the mouth of the harbor. Deeper westward-facing slope sites, especially along the western sides of Western and Jade Shoals, also could be affected by swells from the west and could have communities differing from more sheltered deep slope sites within the turning basin.

In summary, of the 35 new sites, 8 were located at water depths of 30 ft or less, 7 were placed at depths ranging from >30 to 60 ft, and 20 sites were distributed at depths between >60 and 90 ft. Of the 20 deep water sites, 16 were located within the direct impact area and were generally situated along the flanks of deeper reef or “pinnacle” features identified during previous bathymetric surveys. The coordinates of the 35 new sites and their locations within the CVN project area are shown in **Table 5** and **Figure 3a**. **Figure 3b** presents the locations of the total 102 sites surveyed during the Dollar *et al.* and Minton *et al.* 2009 surveys and the Task 1 2010 survey.

Table 5. Geographic Coordinates of the Additional 35 Sites Surveyed Under Task 1

Site No.	X	Y	Latitude (N)	Longitude (E)	Strata				Depth (ft)

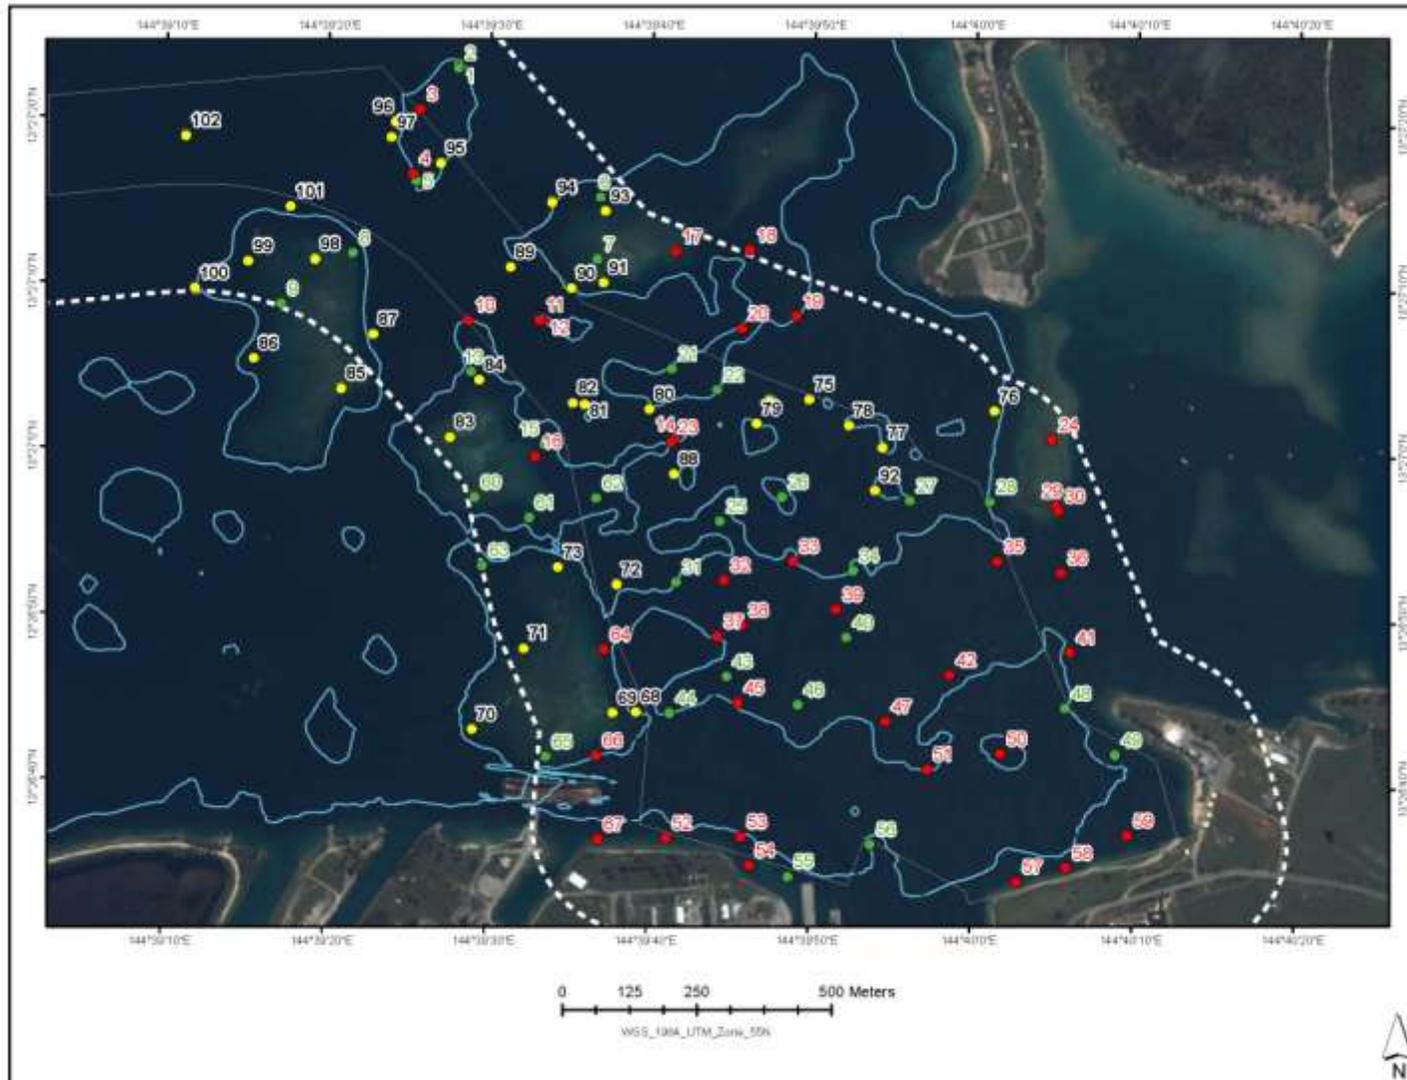

Figure 3b. Locations of the 102 Sites Surveyed in CVN Project Area

3.0 SURVEY METHODOLOGIES

3.1 Survey Methodologies

Field surveys were conducted in Apra Harbor between 8 November and 3 December 2010. Data were collected by trained and experienced marine biologist divers using SCUBA with Nitrox. Diving was conducted from two separate platforms under a Navy-approved Dive Plan that was enforced by designated on-board Dive Safety Officers.

As recommended by the RA, the survey and dive team included the following four independent coral experts:

- Dr. Steven Coles, Bishop Museum, Hawaii;
- Dr. Douglas Fenner, Department of Marine and Wildlife Resources in American Samoa;
- Dr. Yimnang Golbuu, Palau International Coral Reef Center; and
- Mr. Victor Bonito, Director of Reef Explorer Fiji.

Information on the other dive team members and brief bios of these coral experts are provided in **Appendix B**.

Prior to the start of the field surveys, the coral experts attended a 3-day, hands-on training workshop that was led by RA representatives Gerry Davis, Steve Kolinski, and Valerie Brown. The training session was intended to calibrate the experts to the coral reef data collection protocols previously used by the RA to conduct benthic community surveys at the 30 sites reported by Minton *et al.* (2009).

Data were collected along temporary sites established at each survey site². For the 35 newly established sites, the diver support vessel deployed a weighted buoy at the selected differential global positioning system (DGPS) coordinates for each site. The first dive team then entered the water at the buoy location and, upon reaching the bottom, established the survey transect using a fiberglass measuring tape originating at the weight and following along the isobath in a standard direction to reduce observer bias. For sites located on slopes, the dive team first swam to the pre-selected water depth before setting up the transect. For sites where the bottom topography was flat, the transects were laid out from south-to-north. General site descriptions and observations also were recorded by the first dive team.

During this supplemental survey, for the original 37 sites surveyed by Dollar *et al.* in 2009, the weighted surface buoy was deployed at the reported global positioning system (GPS) site position. Divers then entered the water, proceeded to the bottom, and established transects at the nearest point having the originally reported water depth. The DGPS unit used during the 2010 supplemental survey had an accuracy from 1 to 2 m while the type of hand-held GPS receiver used during the 2009 surveys typically has an accuracy of about 10 m. Due to this difference in instrument accuracy, the resulting geographic coordinates displayed by the DGPS in 2010 did not necessarily correspond with the actual specific locations surveyed in 2009. Because of this

² Within this report the terms “site” and “transect” both refer to the designated location surveyed and are essentially interchangeable.

difference, many of the transects reestablished during this survey were potentially at a distance from the original 2009 transect locations and, in some cases, bottom habitat and features were quite different.

Transect survey methods were based on methodologies recommended by Minton *et al.* (2009). At each station, a 25-m by 4-m data collection quadrant (DCQ) was established (**Photo 1**) and proposed data were collected.

Photo 1. Marine scientist establishing the 25-m transect along a specific depth contour

3.2 Coral

Coral data were collected within the first 10 m of the survey quadrant at each station by dive teams comprised of the listed coral experts. Data were collected at 1-m intervals by centering a 1-m² quadrat frame along the transect axis to define sampling boundaries. Each coral expert located all coral colonies whose center fell within the quadrat and identified them to the lowest feasible taxonomic level. Individual coral colonies were distinguished and recorded by a variety of factors including color, morphology, and tissue or skeletal boundary separation, which were used to determine sizes of individual colonies. Growth forms of each individual colony also were determined and recorded.

Colony centers and boundary delineations were identified in a diligent manner to ensure that colonies that fell within multiple quadrats were counted only once within each 10-m transect. For any colony that couldn't be positively identified in the field, multiple photographs were taken to assist with subsequent identification. Photographs also were taken perpendicular to and ~0.75 m above the substratum every half meter along the entire length of the 10-m belt transect. In addition, a series of images of the general habitat were collected along each 10-m belt transect.

Dominant stony corals included *Porites rus*, *Porites horizontalata*, *Porites cylindrica*, *Porites lutea*, and *Pavona cactus*. Delineation of individuals of *P. rus* and *P. horizontalata*, which were the most abundant coral constituent at many of the sites, often involved following and delineating the entire length of the tissue and skeletal boundary as intra-colony variation in color, morphology, and incomplete fusion of overlapping or adjacent tissue areas occurred. Skeletal formation and direction formed the major basis of colony delineation for *P. cylindrica* when tissue necrosis at branch bases and partial burial was found. Thick, extensive fields of *P. cactus* could sometimes not be reliably distinguished on an individual colony basis. When this situation was encountered, measurements were made specific to recognizable clumps or aggregations, and labeled as such.

All coral fragments at the site, defined as any unattached coral piece physically dissociated from a “parent” colony of skeletal and tissue material, were counted, identified to the lowest possible

taxonomic level, and sized separately and designated as fragments. At sites where *P. cactus* fragments could not be feasibly counted, their presence was noted. Fragments that were obviously recently broken (e.g., broken surface bone-white with rough intact skeletal porosity and no apparent overgrowth) were not counted because it was assumed these coral pieces were broken during the performance of this study.

The longest axis of each coral colony and fragment whose center fell within a quadrat was measured using a meter stick with 10-centimeter (cm) gradations or, for smaller colonies, a flexible 1-cm delineated measuring tape. Based on measured size, colonies were placed into one of nine sizes classes: <2 cm, 2 to <5 cm, 5 to <10 cm, 10 to <20 cm, 20 to <40 cm, 40 to <80 cm, 80 to <160 cm, 160 to <320 cm, and ≥ 320 cm.

If separate pieces of attached tissue appeared to be parts of a single individual colony (based on color, morphology, or skeletal connectivity) that had undergone partial mortality, the separate pieces were considered part of an individual colony that had undergone complete fission and a visual estimate of percent tissue mortality of the fissioned colony was made. A fissioned colony was sized as a single measure across the longest diameter of the underlying skeleton (when readily discernable) or between the outermost boundaries of the farthest pieces of colony tissue. As applicable, percent dead tissue was also recorded. If colonies had undergone partial mortality and had only 1 piece of living tissue remaining, the data was recorded similar to fissioned colonies.

As bottom time allowed, coral experts surveyed an approximately 5-m wide band along each side of the 10-m coral transect. This was accomplished by slowly swimming parallel to each side of the 10-m transect searching for corals not recorded along the original 1-m width transect. Coral species not previously observed within the 1-m width transect quadrats were recorded.

3.3 Algae and Sessile Non-Coral Invertebrates

Algae and sessile non-coral invertebrate data were collected in 10 separate 1-m by 0.67-m subquadrats along each transect by marine scientists experienced in the method of *in-situ* identification of marine algae and invertebrates (**Photo 2**). These contiguous quadrats were placed along the centerline within the first 6.7-m by 1-m section of the 25-m by 4-m DCQ established at each survey station.

Benthic taxa were visually estimated to the nearest 1% cover. To assist with these visual estimations, each quadrat was strung to contain a grid in which each square represented 6.25% of that quadrat. When appropriate, overlying

Photo 2. Marine scientist collecting algae and sessile invertebrate data within the 0.67-m by 1-m subquadrats along a shallow reef slope site transect (note large *Lobophyllia* sp.)

algae were gently waved aside so that estimates could be made down through the “canopy” layers. As a result, a total coverage estimate in excess of 100% could result if a community had a well developed canopy or understory layers. Rare taxa were assigned a cover of 1%. All taxa were identified to the lowest feasible taxonomic level and, as necessary; specimens were collected to confirm field identifications in the laboratory. When necessary, representative specimens of macroalgae were returned to the office and examined under a dissecting microscope to confirm identifications. All quadrats were photographed to assist with data verification and for archiving.

Upon completing the 6.7-m by 1-m belt transect, divers visually surveyed an approximately 5-m width belt on either side of the transect line and noted the presence of benthic species that were not observed within the belt transect. To enhance sampling efficiency and avoid overlap, the coral and mobile non-coral invertebrate surveys and the algae and sessile non-coral invertebrates surveys were conducted on alternate dives.

3.4 Mobile Non-Coral Invertebrates

All unattached, non-coral macro-invertebrates observed within the 25-m by 4-m DCQ were documented and identified to the lowest feasible taxonomic level. As directed in the scope of work and due to significant time constraints observations were made without disturbance to the site and with only brief checking of crevices.

3.5 Rugosity

A light brass chain marked at 1-m intervals was draped over the bottom along the first 10-m section of the transect line, corresponding to the segment surveyed for corals and attached algae and sessile non-coral invertebrates. The rugosity index was calculated by dividing the total length of chain draped over the reef surface by the linear distance between the two end points of the chain, in this case 10 m. A value of one indicated a flat bottom; higher values correspond with increased bottom rugosity.

3.6 Incidental Sightings of Marine Mammals and Reptiles

Incidental sightings of marine mammals and reptiles were noted when observed. The latitude and longitude, or the site number of the nearest sampling station to the observation point, were taken and the mammals or reptiles were photographed, if possible.

3.7 Survey Data Compilation

At the conclusion of each survey day, members of each dive survey team discussed the results of the day’s sampling and compared identifications and individual results to ensure consistency of identification among the two teams. All data then were transferred from the original waterproof data sheets onto Excel spreadsheets in a flat-file format, and all photographic data were downloaded.

4.0 OBSERVATIONS

4.1 General Description of Survey Sites and Transects

The harbor area survey was conducted at sites within and adjacent to the proposed CVN project area. **Table 6** lists the 37 survey transects from the Dollar *et al.* study and the 35 new transects selected for this survey (72 total survey transects), physical habitat types, water depths, and general site descriptions. Areas surveyed included shallow reef flat sites, outboard (higher-energy) and inboard (lower-energy) shallow reef slopes, deep reef and macroalgae flats, deep reef slopes, and northern pinnacles. Bottom substrates ranged from a nearly 100% cover of living coral structures to mixed coral cover sites to coral rubble and unconsolidated sediments to fine silty/sand-covered bottom. The sites included high percent cover of coral communities dominated by a *Porites rus* and *Porites horizontalata* complex, mixed coral communities with higher diversity coral and sponge assemblages, areas of relatively dense macroalgae, depauperate silty-sand bottom areas, and various combinations of these habitats.

Table 6. General Descriptions of the 72 Task 1 Survey Sites

Physical Habitat Description	Site Number	Water Depth (ft)	Down-slope Direction	Flat/Slope	Date Surveyed	Brief Site Description
Shallow Reef Flat	24	5	None	F	11/12/2010	Shallow reef flat/crest; sand and corals
	29	5	None	F	11/12/2010	Shallow reef flat with <i>Porites</i> heads
	69	7	None	F	11/18/2010	Shallow reef crest with rubble and debris; <i>Padina</i> and invertebrates
	83	4	None	F	11/15/2010	Shallow reef flat with low coral cover and high invertebrate density
	93	5	None	F	12/2/2010	Shallow reef crest with corals
	98	7	None	F	11/15/2010	Reef flat with heavy <i>Padina</i> cover and scattered corals
Outboard (higher-energy) Shallow Reef Slope	70	20	SW	S	11/16/2010	Shallow vertical face of west side of Big Blue Reef; high coral cover
	71	30	WNW	S	11/16/2010	Shallow slope on west side of Big Blue Reef with high <i>Porites rus</i> cover
	84	39	NNW	S	11/15/2010	Shallow slope on No-name shoal with high coral cover/diversity
	91	34	SSW	S	11/17/2010	Shallow slope along Jade Shoals; high coral cover
	99	30	W	S	11/15/2010	Slope dominated by <i>Porites rus</i> , with sponges and patches of <i>Halimeda</i>
Inboard (lower-energy) Shallow Reef Slope	17	8	SE	S	11/8/2010	Just below edge of shallow reef flat
	30	12	SE	S	11/11/2010	Shallow reef slope with high coral cover
	73	22	N	S	11/18/2010	Shallow slope with coral rubble, macroalgae, and coarse sand
	76	40	W	S	11/16/2010	Shallow slope site; few corals with rubble and coralline algae

Shallow reef flat sites included Transects 24, 29, 69, 83, 93, and 98, which were positioned at the crests of Jade Shoal, Western Shoal, Middle Shoal, Big Blue Reef, and the shoal between the CVN project area and Sasa Bay to the east, at water depths ranging from 4 to 7 ft. These sites typically comprised areas of mixed stony corals (primarily *Porites lutea* and other massive *Porites* species, *Porites cylindrica*, and *Porites rus*) along with macroalgae, sponges, sand, and coral rubble (**Photo 3**).

Photo 3. Coral expert censusing stony corals within a 1-m² quadrat at shallow reef flat Transect 98. Note high cover of the algae *Padina* sp., along with the stony corals *Acropora latistella* (purple, center) and two colonies of *Pocillopora damicornis* to the left and right of the tape adjacent to the *A. latistella*.

Shallow reef slope sites, stratified as outboard (higher-energy) or inboard (lower-energy), were positioned along the margins of the previously listed shoals and reefs as well as along the southern shoreline of the harbor. The transects along the reef and shoal margins ranged from 8- to 40-ft depths, and were generally high in living coral cover (**Photo 4**), with a significant macroalgal component at several locations. The shallow slope sites along the southern shoreline of the harbor, more appropriately described as shallow rubble sites, were seven locations previously surveyed by Dollar *et al.* in 2009. These sites ranged from 4- to 58-ft depths and were primarily characterized as sandy and rubble-covered slopes with low numbers of small coral colonies and minimal macroalgae cover.

Photo 4. Shallow reef slope site on Big Blue Reef with nearly 100% coral cover composed of *Acropora latistella* (left center) and *Porites rus* (possibly combined with *Porites horizontalata*) in remainder of photograph.

Deep reef flat sites were found within the southern harbor turning basin and on the tops of several smaller “pinnacles,” which had been dredged down to about 40 to 45 ft depths during the 1946 harbor dredging project. Water depths along these transects ranged from 42 to 60 ft. Transects positioned within these areas included habitat consisting of dense beds of macroalgae (primarily *Halimeda* spp., *Caulerpa* spp., and *Padina* sp.) (**Photo 5**), with intermixed scattered patches of stony corals and sponges, along with areas of bare sandy-silt sediments.

Deep slope sites were located along the periphery of the shallow reefs and shoals as well as off the edges of the large deep reef flats within the turning basin at water depths

ranging from 51 to 90 ft (**Photo 6**). Actual slopes ranged from very gradual near the bases of the features to nearly vertical. Typical biota included corals, ascidians, sponges, bryozoans, and macroalgae in highly diverse distributions. Areas of bare sandy-silt substrate were often interspersed with low-to-high coral and macroalgae cover along various sections of the same survey transect.

Photo 5. Deep reef flat Site 12 with heavy percent cover of *Halimeda* sp.

Photo 6. Deep slope Site 95 with sponges *Melophlus sarasinorum* (lower left corner) and *Iotrochota ditrochota* (branching, lower right) along with a plating form of the stony coral *Porites rus* (center, upper left).

The northern pinnacles sites were positioned within the area of direct impacts on an arc of small pinnacle features along the northern edge of the wider turning basin area, as well as on a pinnacle on the channel centerline slightly to the west-northwest. These also were predominantly deep

slopes falling at water depths of 65 to 89 ft and with silt-covered rubble bottom along with sponges, algae, and occasional corals.

4.2 Corals

A total of 57 distinct coral species were identified by the coral experts along the 10-m by 1-m transects at the 72 sites surveyed. An additional 35 coral species were noted within 5 m to either side of the 10-m coral transects, for a total of 92 distinct coral species observed along the transects (**Table 7**). A total of 4,061 coral colonies were identified and counted along the 10-m transect segments; *Porites rus* (1,891 colonies) and *Porites horizontalata* (811 colonies) were the two most abundant species, comprising 66.5% of the total number of observed corals (**Appendix C**). Other relatively common species included *Pavona cactus* (384 colonies), *Porites cylindrica* (136 colonies), *Leptastrea purpurea* (118 colonies), *Pocillopora damicornis* (117 colonies), and *Porites lutea* (112 colonies) (**Figure 4**).

The longest axis of each coral colony observed along the 10-m by 1-m transects was measured and entered into one of the following size classes: <2 cm, 2 to <5 cm, 5 to <10 cm, 10 to <20 cm, 20 to <40 cm, 40 to <80 cm, 80 to <160 cm, 160 to <320 cm, and >320 cm. Of the 4,061 total coral colonies identified along the transects, 30.6% (1,244 colonies) fell within the 5- to <10-cm size class and 27.4% (1,111 colonies) fell within the 10- to <20-cm size class. Size class distributions of the seven most commonly observed species within the harbor are shown in **Figure 5**. A total of 341 colonies, or 8.4% of the observed corals, exceeded 40 cm along their longest axis and only 95 colonies (2.3%) were larger than 80 cm. Of the colonies greater than 40-cm size, 75% (256 colonies) were either *Porites rus* or *Porites horizontalata*.

Coral species number and density along individual survey transects are illustrated in **Figure 6**. Along the shallow reef flat transects, coral densities ranged from just under 1 to 20.6 colonies per m², averaging 5.9 colonies per m², with an average of about 6 coral species identified per 10-m transect. The most abundant corals along these transects were *P. damicornis*, *P. rus*, *P. cylindrica*, *Pavona decussata*, *P. lutea*, and *Leptastrea purpurea*.

Of the 10 shallow reef slope transects, the five outboard (higher-energy) transects (Sites 70, 71, 84, 91, and 99) had relatively high coral densities ranging from 5.0 to 20.3 colonies per m² and averaging 14.5 colonies per m², while the five inboard (lower-energy) shallow reef slope transects (Sites 17, 30, 73, 76, and 85) had lower densities of 0.8 to 6.3 colonies per m² and an average density of 3.2 colonies per m². This difference in density may be partially attributed to the first five sites having a more open westward exposure to wave energy from the mouth of the harbor, lessening the negative impacts from siltation and sediment accumulation and providing greater water circulation. Despite the difference in coral densities, the average coral species richness within the two strata was closer, at 7.8 species per transect for the higher-energy sites and 5.2 species per transect for the lower-energy sites. This was partially due to the dominance of *Porites rus* along higher-energy Transects 91 and 99 with only 3 and 1 documented coral species, respectively.

35 additional species occurred within 5 m of transect centerlines.

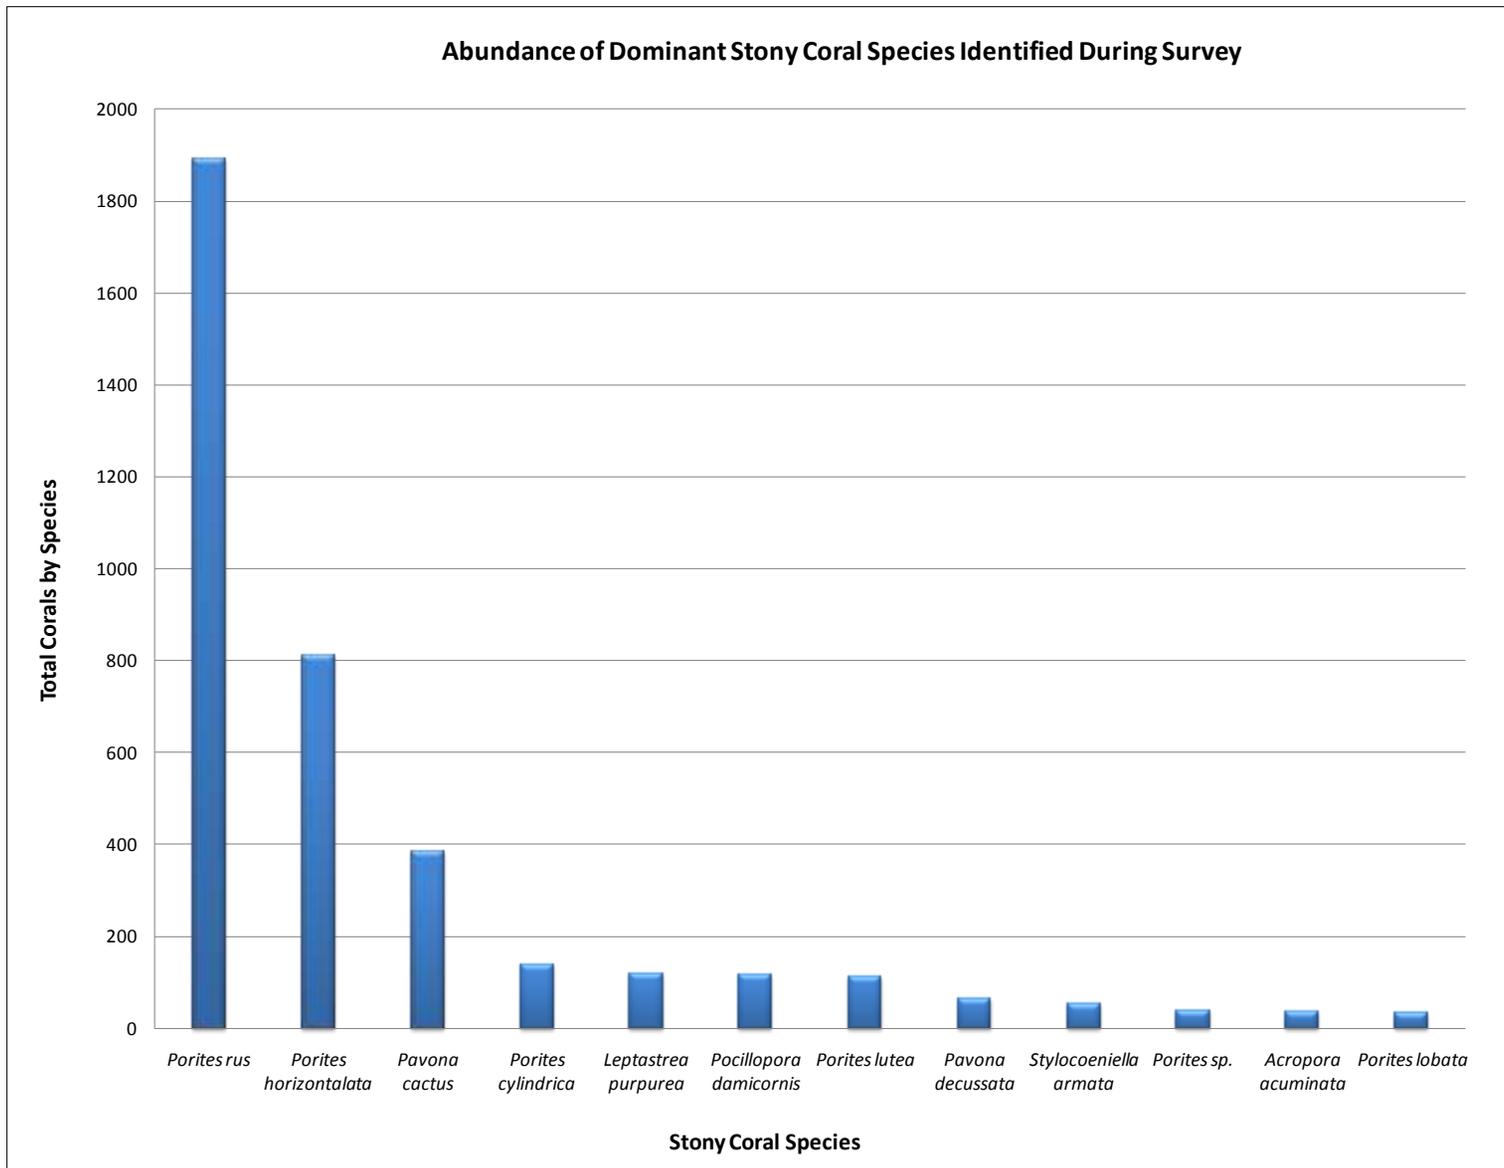

Figure 4. Abundance of Dominant Stony Coral Species Identified During the Survey

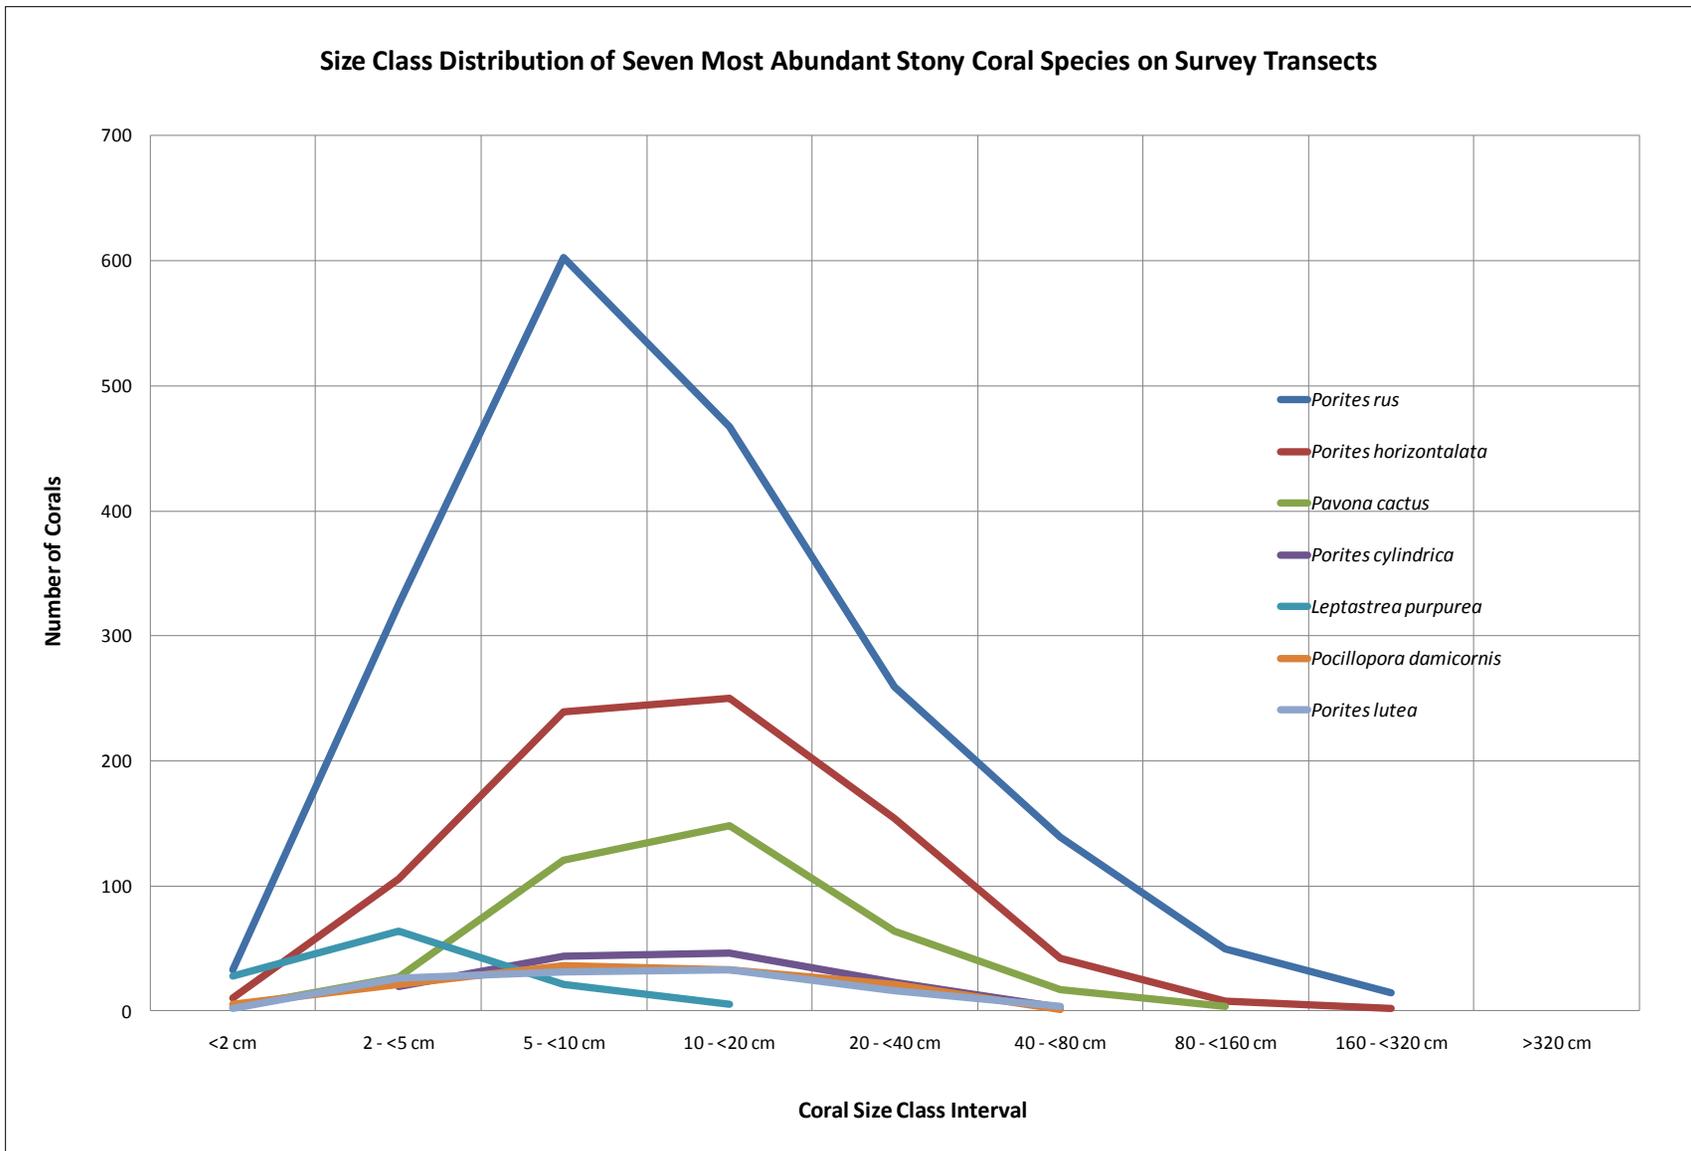

Figure 5. Size Class Distribution of the Seven Most Abundant Stony Coral Species Along Survey Transects

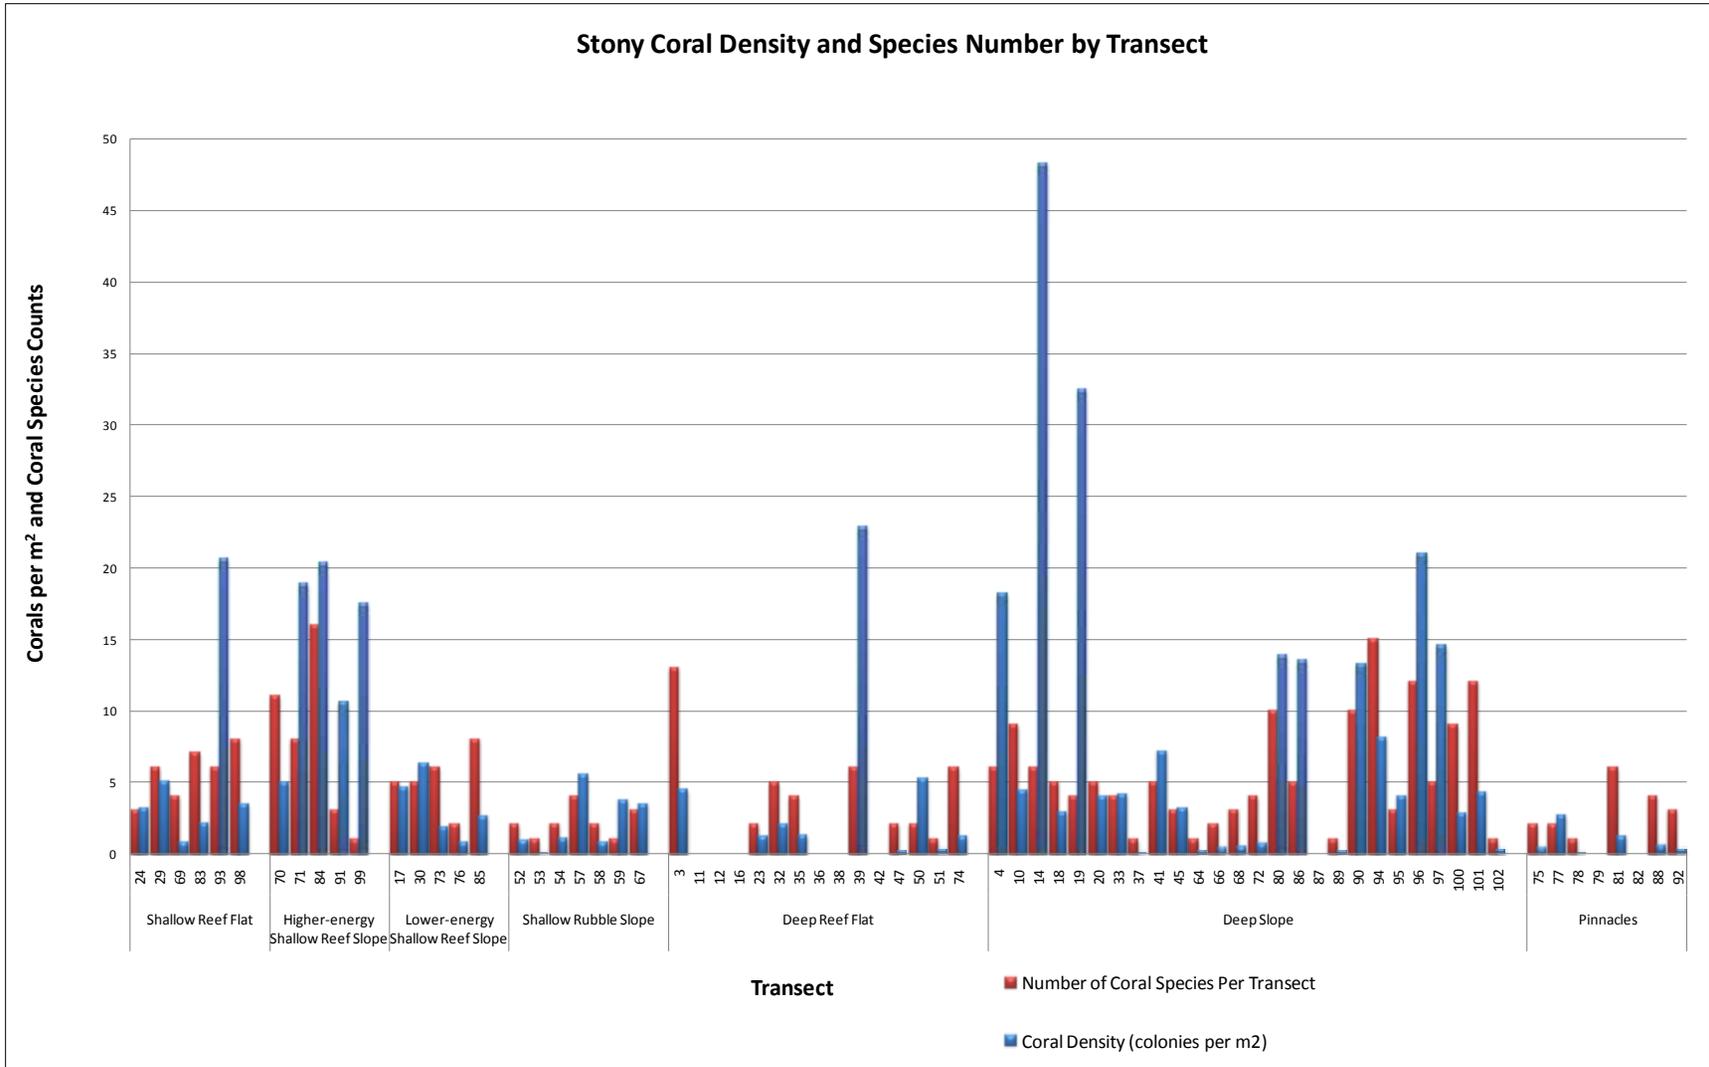

Figure 6. Stony Coral Density and Species Number Along 10-m by 1-m Survey Transects

The shallow rubble slope transects along the southern edge of the harbor, as would be expected, exhibited a much lower coral density and richness, with an average of 2.2 colonies per m² and 2 coral species per transect. The most abundant corals along these transects were *Leptastrea purpurea*, *Porites lutea*, and the acroporid species *Acropora acuminata*, although it occurred only in a small thicket along Transect 59.

The deep reef flat areas in the center of the turning basin generally were low in both coral density and species richness with only 4 of the 15 transects having five or more coral species. All but one transect had a coral species richness of 6 or lower and six transects had no observed corals. This was primarily due to the presence of a large amount of fine surficial sediments, in combination with high macroalgae percent cover over large expanses of the bottom. Essentially these sites had been previously dredged and provided minimal hard bottom substrate to which corals could attach.

Deep slope transects exhibited a wide range of coral density from no corals along Transect 87 to 48.3 colonies per m² along Transect 14, the highest density observed along any single survey transect. Seven additional transects (4, 19, 80, 86, 90, 96, and 97) had coral densities of greater than 10 colonies per m². However, along these eight higher coral density transects, the three species *Pavona cactus*, *Porites horizontalata*, and *Porites rus* comprised between 89% and 99% of the corals identified. Six of the eight transects with highest coral density exhibited either an open exposure to ocean swells moving through the harbor from the west or a somewhat open exposure and water depth of less than 70 ft. The two transects not exposed to the west and still having a high coral density were Transects 19 and 80 with 32.5 and 13.9 colonies per m², respectively. Transect 19 was positioned along a southeast-facing slope but was in a relatively shallow depth just below an area of well-developed reef. Transect 80 fell along a steep ~60° downward slope to the south, preventing a significant accumulation of sediments, and comprising about 50% sandy-silt bottom and coral rubble and 50% healthy colonies of *Pavona cactus* and *Porites rus*.

The eight pinnacles transects all had low coral density with the highest along Transect 77 at 2.7 colonies per m². Species richness also was low, ranging from no coral species along two transects up to six species on Transect 81.

A total of 258 (6.4%) identified coral colonies exhibited some percentage of dead tissue or skeleton, ranging from 1% to nearly 100% dead. Of the 258 partially dead colonies, 155 colonies (60.1%) were *Porites rus*, 37 colonies (14.3%) were *Porites horizontalata*, 10 colonies (3.9%) were *Porites lutea*, 8 colonies (3.1%) were *Porites cylindrica*, and 6 colonies (2.3%) were *Pavona cactus* (**Table 8**). A total of 39 of the 63 transects containing identified coral colonies had corals with some level of mortality. Within this subset of 39 transects and along those transects having 50 or more observed coral colonies, the percentage of corals showing partial mortality ranged from 0.9% (1 of 106 colonies) along Transect 91 to 24% (12 of 50 colonies) along Transect 70.

Fragmentation of observed coral colonies also was recorded along the 10-m coral transects, with fragmented colonies noted along 30 of the 63 coral-bearing transects containing corals.

A total of 416 coral fragments were identified with the majority occurring along Transects 14 (57 fragments), 91 (46 fragments), 90 (43 fragments), 30 (36 fragments), and 19 (33 fragments) (**Table 9**). Stony coral species with the highest number of fragmented colonies included *Porites rus* with 172 fragmented colonies, *Pavona cactus* (142), *Porites horizontalata* (26), and *Pocillopora damicornis* (22); all were branching or thin plating coral species (**Figure 7**).

During this survey, the participating coral experts found what could potentially be new coral species records or range extensions for Guam as well as several coral species that may be undescribed. The presence of *Pectinia ~alicornis* (photographs in **Appendix D**) may be a new record for Guam. *Pectinia ~alicornis* was observed within the 5-m area adjacent to Transects 33 and 50. Coral species that are also new records and may possibly be undescribed include *Fungia* sp. 1, *Fungia* sp. 2, *Montipora* sp. 1, *Montipora* sp. 3, *Montipora* sp. 7, *Montipora* sp. 8, *Montipora* sp. 9, and *Porites* sp. 2 (**Appendix C**). Additionally, it was reported that several coral species that are rare or uncommon on reefs outside the harbor were fairly common inside, including *Lobophyllia robusta*, *Lobophyllia hataii*, *Acropora granulosa*, and *Acropora latistella*.

A few instances of gross growth anomalies or anomalous patterns of coral tissue loss were observed during the surveys.

4.3 Macroalgae and Sessile Invertebrates

Figure 8 illustrates percent cover data for macroalgae and sessile invertebrates identified along each of the 6.7-m by 1-m transect segments. Cumulative biotic percent cover ranged from as low as 1% in areas of sandy-silt and rubble-covered bottom to 100% at several sites with high stony coral and/or macroalgae cover (**Appendix E**). Relatively abundant macroalgae species within the project area in order of decreasing abundance included *Caulerpa verticillata*, *Dictyopteris repens*, *Halimeda* spp., *Caulerpa sertularioides*, unidentified crustose coralline algae, and *Padina* sp. Abundant sessile invertebrates within the CVN Transient Pier Project Area were comprised primarily of stony corals, sponges, and ascidians, with rarer groups including anemones, polychaetes, mollusks, and bryozoans. The ascidian *Rhopalaea* sp., the stony corals *P. rus* and *P. horizontalata*, and the sponges *Haliclona* spp, *Clathria eurypa*, *Xestospongia carbonaria*, and *Liosina* sp. were some of the more common sessile invertebrates identified along the transects. Highest coral percent cover predominantly occurs on transects positioned along the edges of the shallow reefs and shoals, while high macroalgae percent cover is more widespread across the survey sites.

4.3.1 Macroalgae

Macroalgae percent cover along individual transects ranged from 0% to greater than 98%, with an average percent cover of 33.8% along all transects. Dominant species included *Caulerpa verticillata*, with an average percent cover of 9.1%, *Dictyopteris repens* with 6.9% cover, *Halimeda* sp. at 2.9%, *Caulerpa sertularioides* at 2.7%, unidentified crustose coralline algae at 1.4%, and *Padina* sp. with 1.3%. Unidentified crustose coralline algae appeared along the largest number of survey transects at 59, with a maximum percent cover of 21.7%.

This was followed by *C. verticillata*, along 54 transects with a maximum cover of 59%; *D. repens*, along 36 transects with a maximum cover of 60.1%; and *Dictyota* sp., along 31 transects with a maximum cover of 9.3%.

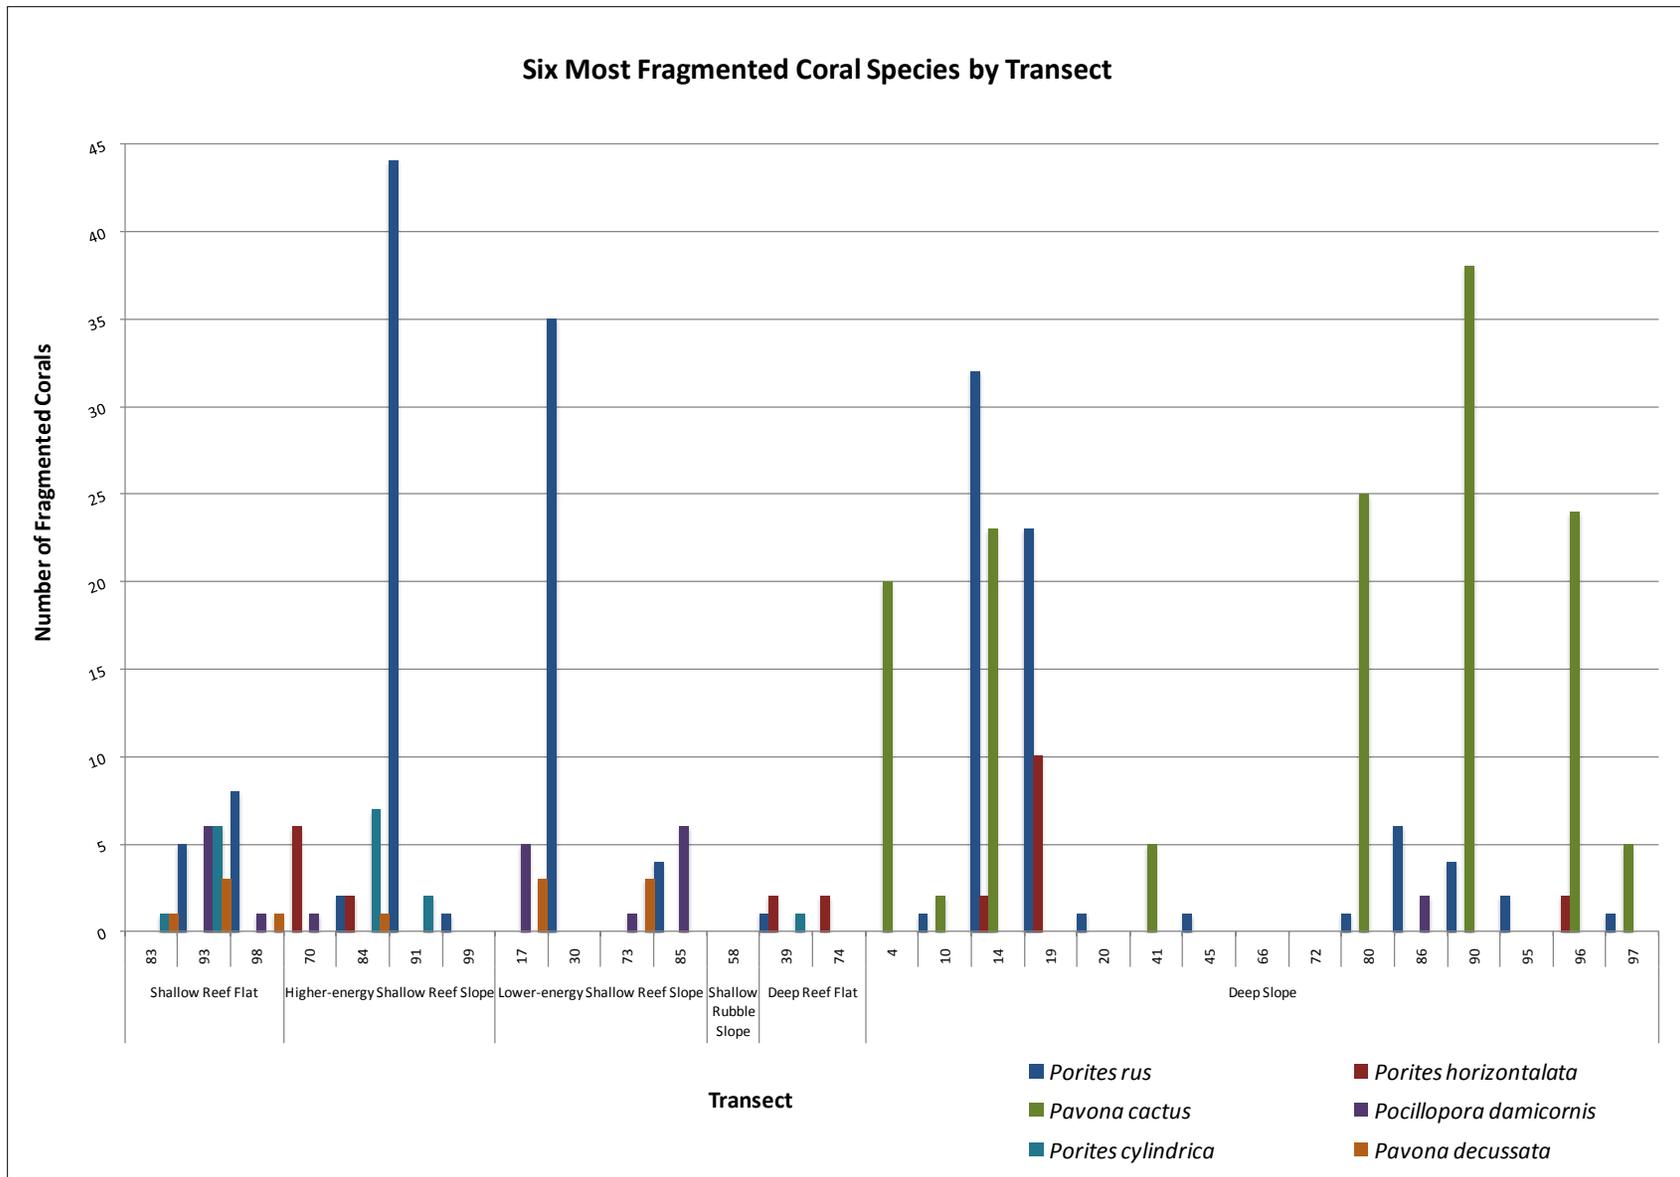

Figure 7. Totals for the Six Most Fragmented Coral Species Along the 10-m by 1-m Survey Transects

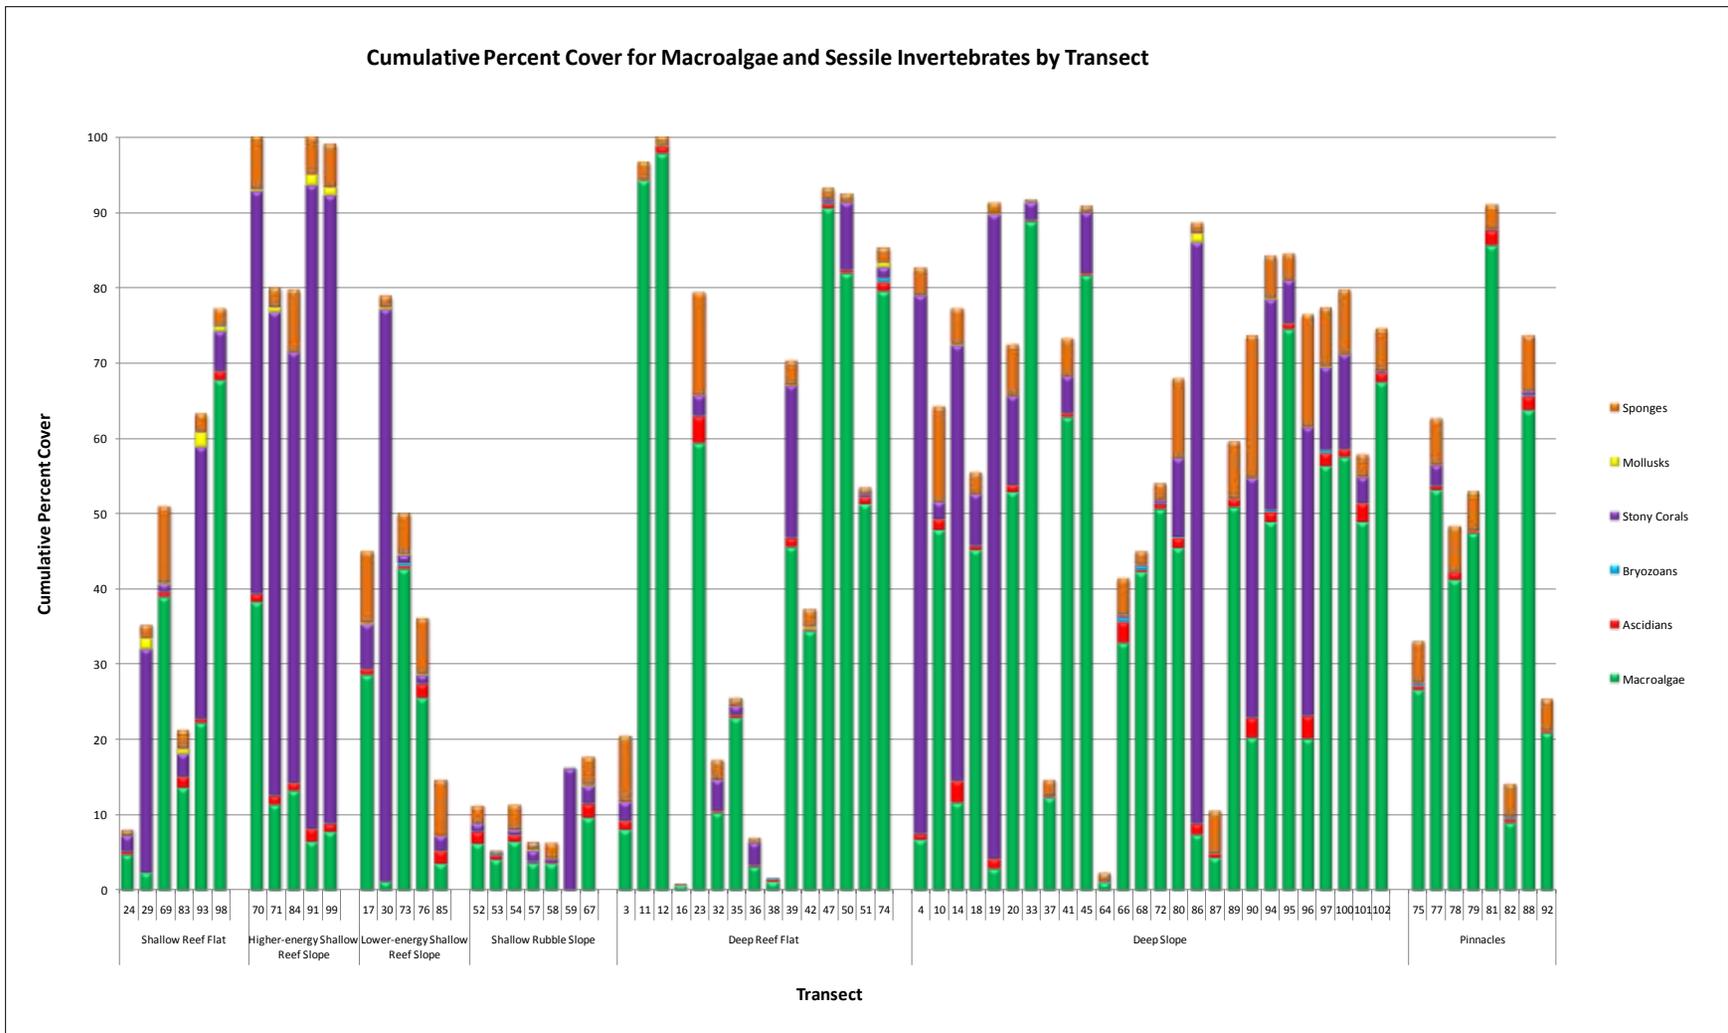

Figure 8. Stony Coral, Macroalgae, and Sponge Cumulative Percent Cover at the 72 Survey Sites

Other widespread macroalgae included *Ralfsia* sp. (26 transects), *Padina* sp. (25 transects), *Halimeda gigas* (24 transects), *H. opuntia* (22 transects), and *Caulerpa racemosa* (21 transects). A total of 66 distinct macroalgae taxa was identified within all of the surveyed 6.7-m by 1-m transect segments (**Table 10**).

<i>Gracilaria</i> sp.	<i>Yamadella</i> sp.

Figure 9 shows macroalgae percent cover totals along each of the survey lines. The shallow reef flat transects had an average macroalgae cover of 25.0%, however, this varied widely among sites, ranging from 2.5% to 67.6% on individual transects. Abundant algae along these shallow transects included *Padina* sp., *Dictyota* sp., and *Halimeda opuntia*.

The shallow reef slope transects had slightly lower average macroalgae percent cover than shallow reef flat sites, at 15.5% cover for the outboard (higher-energy) transects and 20.4% cover for the inboard (lower-energy) sites. Similar to the shallow reef flat transects, algae cover on the shallow reef slope transects also was variable, ranging from 1.3% to 42.7%. More common species included *Ralfsia* sp., *Caulerpa verticillata*, and *Lobophora* spp. at the higher-energy transects and *Padina* sp., *Halimeda opuntia*, and *Halimeda* sp. at the lower-energy sites.

For the shallow rubble slope lines, *Dictyota* spp. and *Padina* sp. were most abundant, although macroalgae average percent cover along these transects was only 4.9%. Macroalgae average percent cover values for the three deeper areas was higher than along the shallow transects with 45.5% cover along the deep reef flat lines, 40.0% cover along the deep slope transects, and 43.4% cover along the pinnacles transects.

Within the deep reef flat areas various species were abundant along different transects with *Halimeda* sp. extensive along Transects 11 and 12, *Dictyopteris repens* with high percent cover at Sites 23, 47, and 74, *Caulerpa sertularioides* relatively abundant on Transects 47 and 50, *Caulerpa verticillata* common on Transect 39, and *Lyngbya* sp. also abundant on Transect 11. Three of these transects (11, 12, and 47) had macroalgae cover higher than 90% while several other sites had less than 5% cover.

Deep slope transects had an average macroalgae cover of 40% and ranged from 1% on Transect 64 to 88.6% on Transect 33. The most common two species were *Caulerpa verticillata* averaging 16.5% cover and found along 25 of 26 deep slope transects and *Dictyopteris repens*, which was identified on 17 transects and had an average cover of 9.7%. The pinnacles transects were virtually identical to the deep slope sites in macroalgae cover with an average of 43.4% per transect. *Caulerpa verticillata* and *Dictyopteris repens* also were the two most abundant species averaging 22.7% and 12.6% cover, respectively.

Small amounts of the seagrass *Halophila* also were noted at several of the deep reef flat and deep slope sites. *Halophila* was observed at the sites in very low abundance with a percent cover of less than 0.5%.

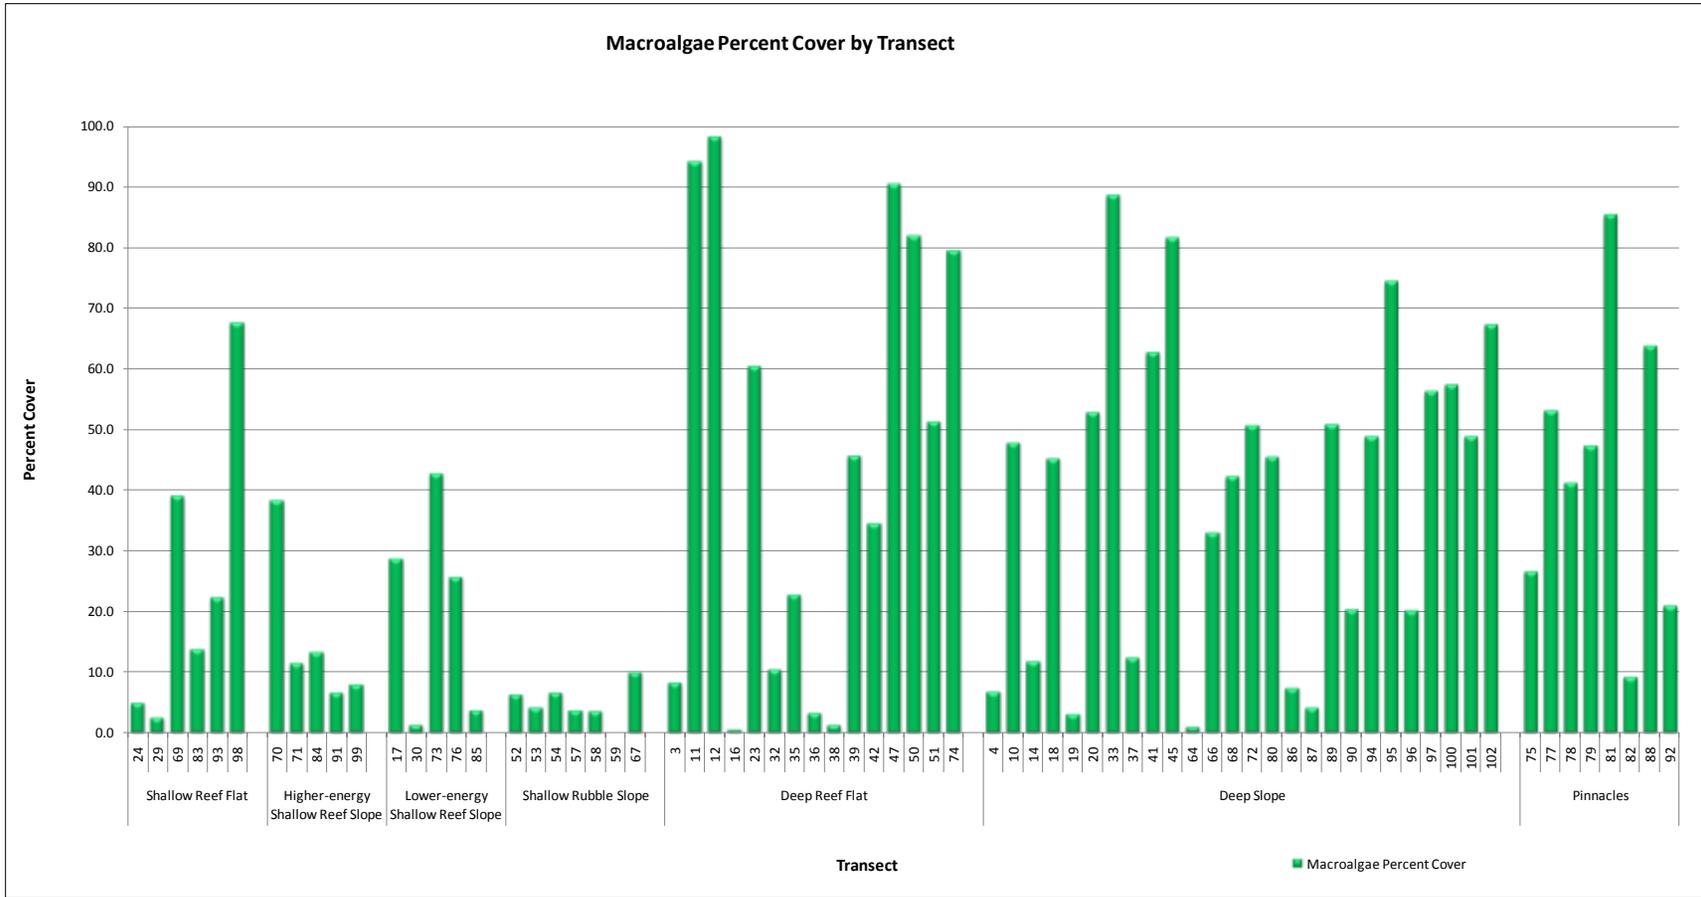

Figure 9. Macroalgae Percent Cover Along the 6.7-m by 1-m Survey Transects

4.3.2 Sessile Invertebrates

Of the sessile invertebrates documented along the survey transects, stony corals were the most abundant and contributed the highest percent cover. Stony coral percent cover ranged from 0% along several of the deep reef flat, deep slope, and pinnacle area transects to more than 75% on three shallow reef slope transects (**Figure 10**). Two of the deep slope sites also had very high percent coral cover values of 77.0% and 85.2%. All five of the outboard higher-energy shallow reef slope transects had coral cover of greater than 50% and averaged 68.9% cover, while the inboard lower-energy shallow reef slope sites averaged only 17.2% coral cover with only one transect exceeding 50% cover. Of the six shallow reef flat transects, Site 93 had 35.9% stony coral cover and Site 29 had 29.6%, while the remaining four sites averaged only 2.9% cover. Four of the 26 deep slope transects exceeded 50% coral cover and overall the deep slope sites averaged 18% cover. None of the shallow rubble slope, deep reef flat, or pinnacles transects had coral cover above 21% and all averaged 3% or lower. Stony coral percent cover across all transects averaged 14.54%.

Coral species were not as widespread as macroalgae with the most common stony coral, *Porites rus*, occurring along 42 transects and with a maximum cover of 83.7%. No other coral species appeared along more than 17 of the 6.7-m transect segments. *Porites horizontalata* occurred along 17 transects with a maximum cover of 23.7%; *Leptastrea purpurea* was identified along 16 transects with a maximum cover of 1%; *Pocillopora damicornis* was on 16 transects with a maximum cover of 5.0%; and *Stylocoeniella armata* occurred along 16 transects with a maximum cover of 0.4%.

A total of 35 distinct stony coral species were identified along the 6.7-m by 1-m macroalgae/sessile invertebrate survey transects, compared to the 57 species observed by the coral experts along the 10-m transects. This difference could be due to a combination of the shorter length of the sessile invertebrate transects and greater experience of coral experts in delineating subtle stony coral species differences.

Sponges also comprised a significant component of the attached epifaunal community with percent cover values exceeding 10% along several transects (**Figure 11**). Average sponge percent cover along all transects was 4.56%. The deep slope transects had the widest range of sponge cover from less than 1% on several lines up to 14.9% on Transect 96 and 18.9% on Transect 90. The lower-energy shallow reef slope sites had the highest average sponge percent cover at 6.3%, followed closely by the outboard higher-energy shallow reef slope sites at 5.9%, the deep slope sites at 5.6%, and the pinnacles transects at 5.3% cover.

At least 37 sponge taxa were identified along the surveyed transects. Common sponge species included *Clathria eurypa* and *Stylinos ruetzleri*, each occurring along 31 transects and having maximum cover of 2.2% and 1.3%, respectively. Other relatively wide-spread sponge species included *Iotrochota ditrochota* (29 transects and 4.7% maximum cover), *Xestospongia carbonaria* (29 transects and 5.8% maximum cover), and *Stylissa massa* (27 transects and 1.7% maximum cover). *Liosina granularis* (observed on 23 transects), *Clathria eurypa*, and *Xestospongia carbonaria* were found within all depth zones and habitats, while *Haliclona* sp. 1 (found on 24 transects) and *Iotrochota ditrochota* were more abundant in the deep slope and deep reef flat areas.

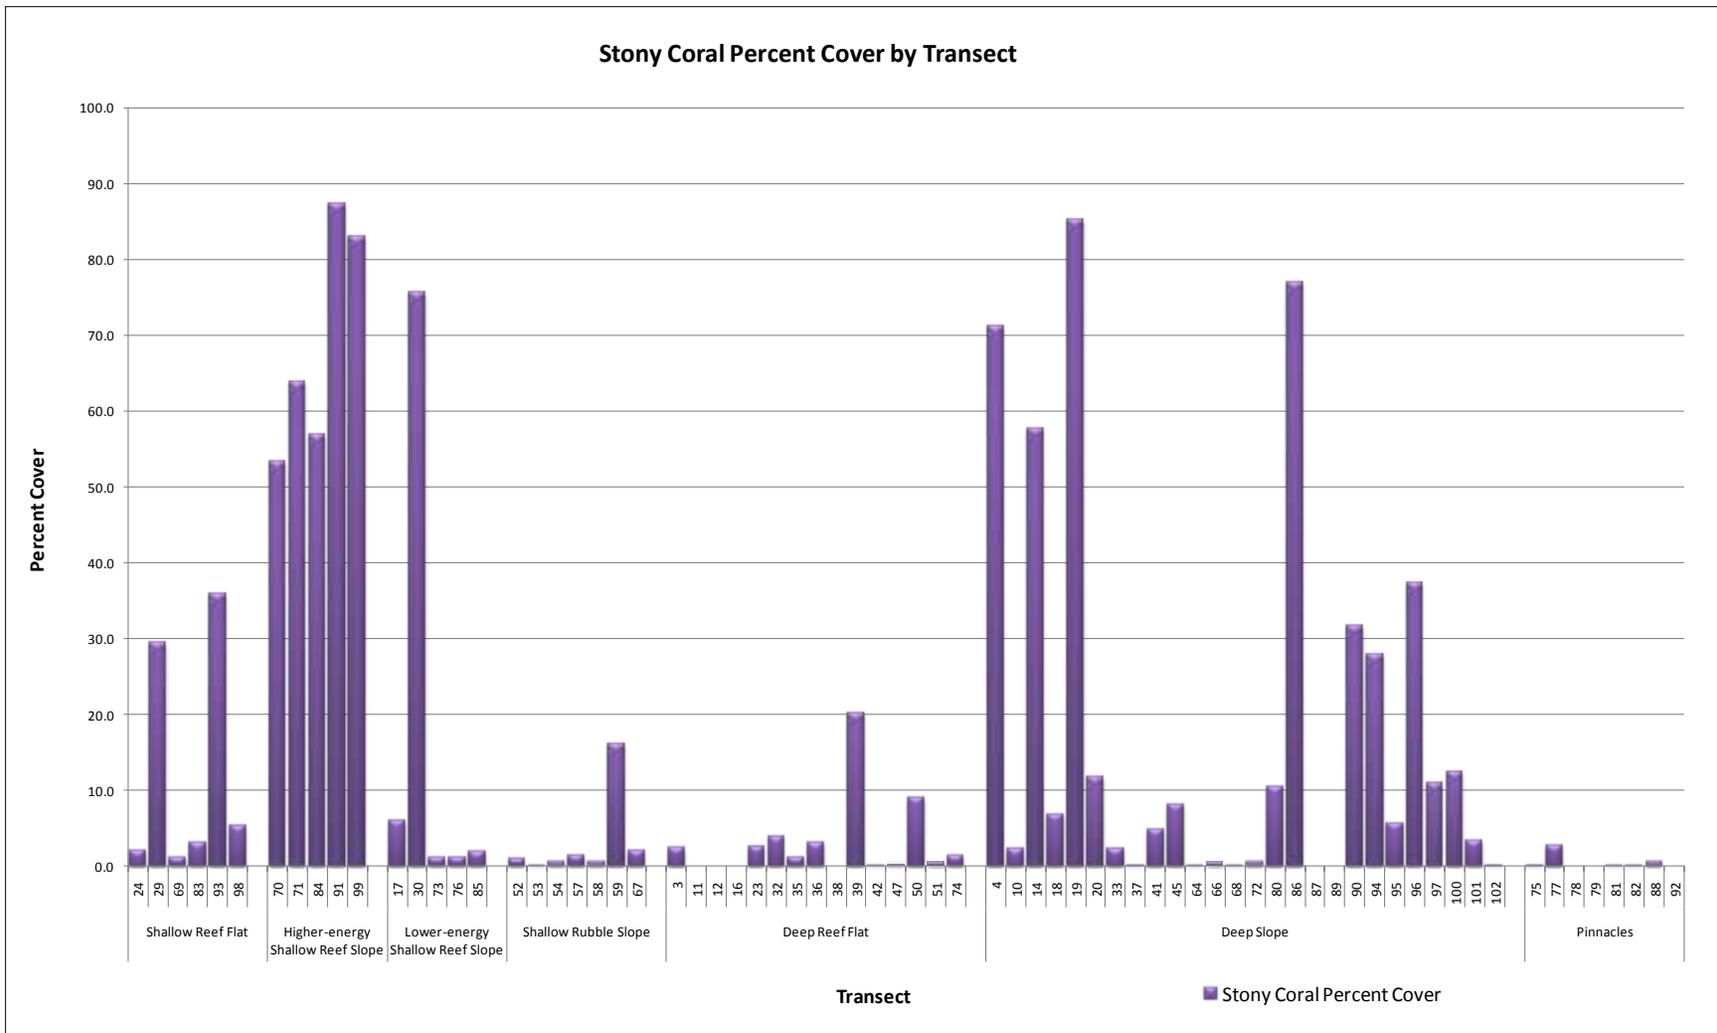

Figure 10. Stony Coral Percent Cover Along the 6.7-m by 1-m Survey Transects

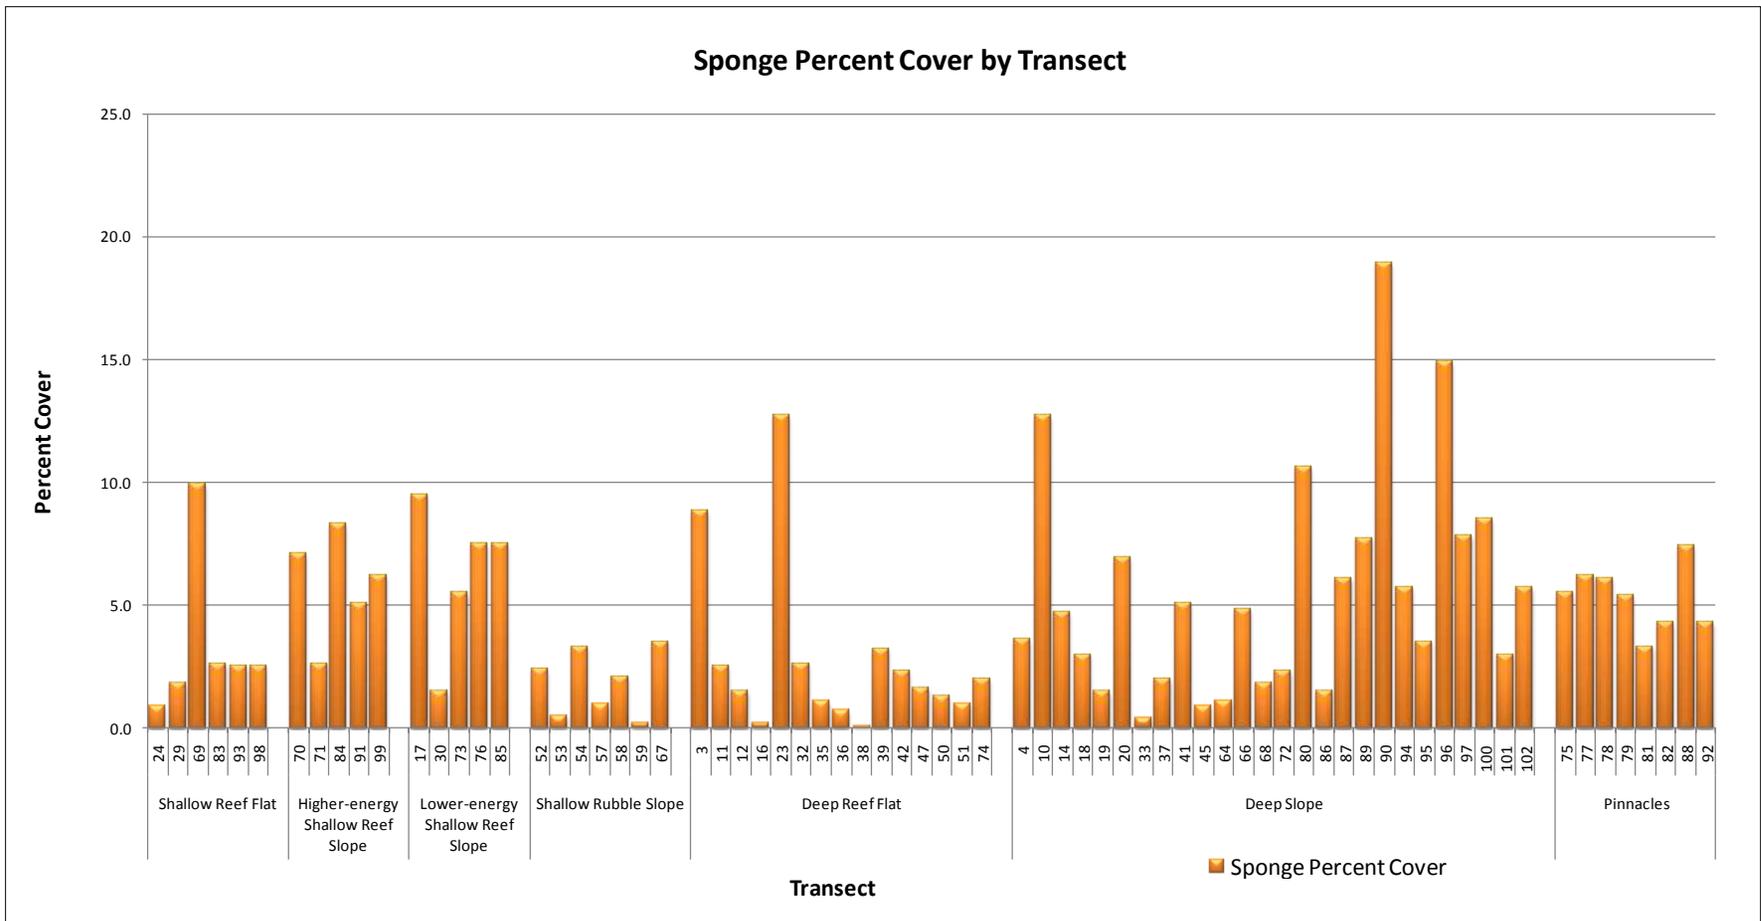

Figure 11. Sponge Percent Cover Along the 6.7-m by 1-m Survey Transects

Although ascidians comprised a relatively small proportion of the biotic percent cover along survey transects, they were common and found throughout all depth zones. Percent cover ranged from 0% to 3.6% and averaged 1.0% over all transects. Ten distinct species/taxa were identified and the more abundant species included *Clavelina* sp., *Phallusia julinea*, *Rhopalaea circula*, and *Rhopalaea crassa*.

Other sessile invertebrates observed along transects included anemones, bryozoans, hydroids, mollusks, polychaetes, soft corals, and zoanthids. All were noted at comparatively low numbers compared to the more abundant stony corals, sponges, and ascidians. Mollusks comprised primarily bivalves attached to the rock substrate, including the genera *Arca*, *Chama*, *Isognomon*, *Lithophaga*, *Malleus*, *Pinctada*, *Pinna*, and *Spondylus*. Polychaetes consisted of the Christmas tree worm *Spirobranchus* sp., which was observed embedded in living coral colonies.

4.4 Mobile Non-Coral Invertebrates

Mobile invertebrate abundance data were collected along the entire 25-m by 4-m transect, or an area of approximately 100 m². A total of 51 distinct taxa from six phyla were identified within the boundaries of the transects (**Table 11**). These included 21 echinoderms, 13 mollusks, 12 arthropods, 3 cnidarians, 1 annelid, and 1 flatworm. The most abundant mobile invertebrate was the shrimp *Periclimenes tenuipes*, with 111 individuals observed. This species was difficult to see due to its small size and nearly clear body, and because of this was most likely present in far greater abundance than reported. *Alpheus* sp., a burrowing alpheid shrimp nearly always observed partnered with a goby, was the next most abundant species with 92 individuals reported. Other relatively abundant species included *Strombus luhuanus* (52), *Holothuria atra* (46), *Bohadschia argus* (30), and *Culcita novaeguineae* (25). These same six species also occurred along the most transects: *Periclimenes tenuipes* (24 transects), *Culcita novaeguineae* (17 transects), *Bohadschia argus* (15 transects), *Alpheus* sp. (13 transects), *Holothuria atra* (8 transects), and *Strombus luhuanus* (7 transects).

The highest abundance of mobile invertebrate species was found along the shallow reef flat transects with an average of 30 individuals per transect (0.3 individuals per m²), followed by the shallow rubble slope areas with 21 individuals per transect (0.21 per m²) (**Figure 12**). Outboard higher-energy shallow reef slope transects averaged 13 individuals per transect (0.13 per m²) followed by 8.0 (0.08 per m²) on the lower-energy shallow reef slope transects, 6 (0.06 per m²) on the deep reef flat lines, and 5.1 individuals per transect (0.05 per m²) on the deep slope transects. Individual transects with the highest mobile invertebrate abundance were Transects 57, 29, and 24. Transect 57, with 71 observed mobile invertebrates (0.7 per m²), was a shallow rubble site at 4-ft depth with a high number of alpheid shrimp along with many *Strombus luhuanus*, a gastropod mollusk. Transects 29 and 24 were both shallow reef flat sites, with Transect 29 containing a large number of alpheid shrimp, while Transect 24 had high numbers of both *Strombus luhuanus* and the sea cucumber *Holothuria atra*.

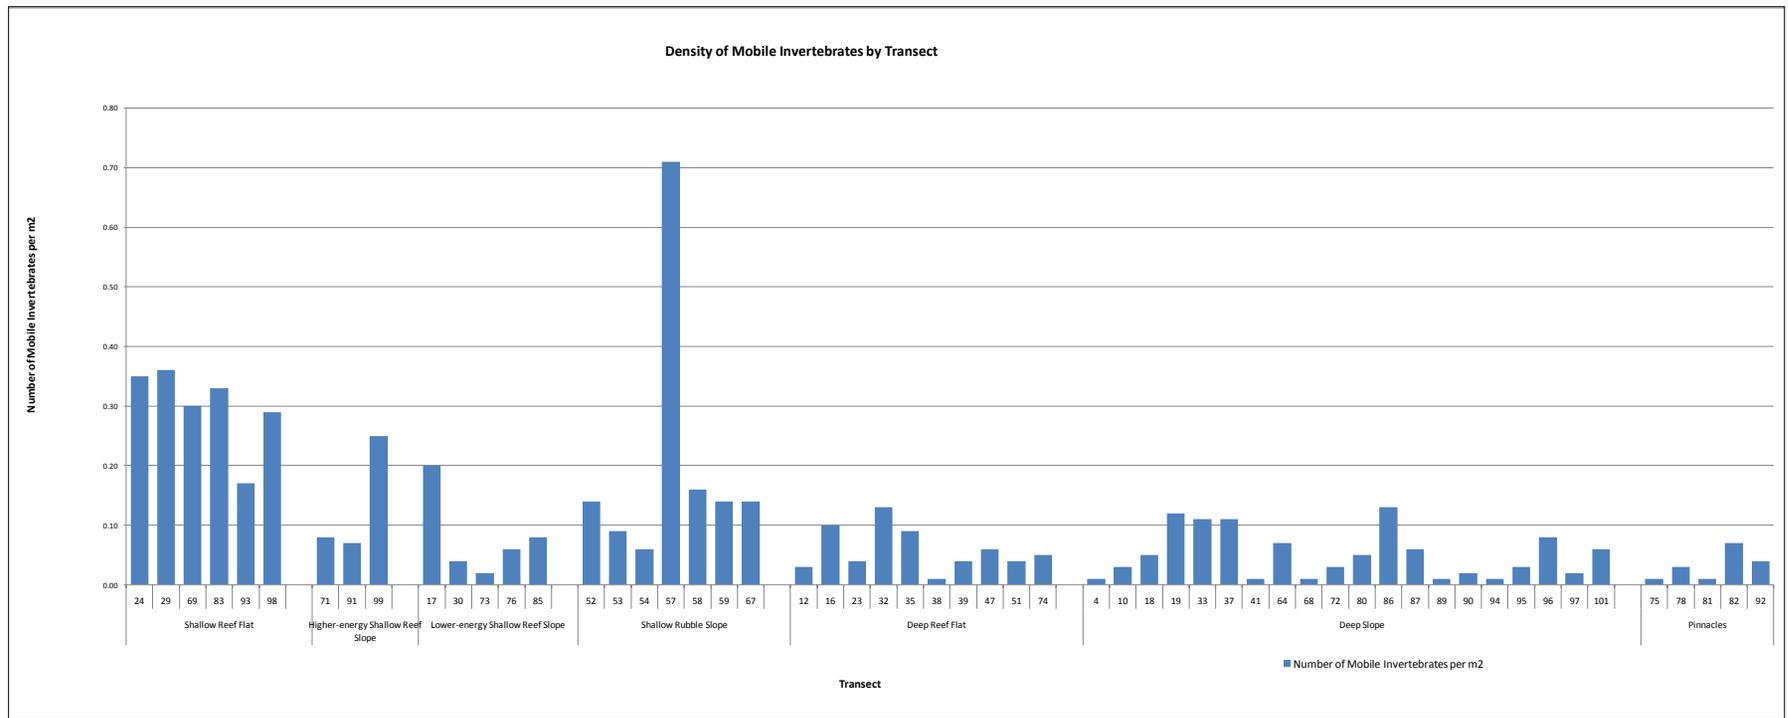

Figure 12. Mobile Invertebrate Density Along the 25-m by 4-m Survey Transects

Generally, asteroids, holothuroids, and echinoids were predominantly observed in the shallower reef flat areas with slightly lower abundance in the shallow rubble slope and shallow reef slope areas and a very low presence in the deep reef flat and deep slope areas. The only exception was the cushion star *Culcita novaeguineae*, which was observed in all water depths. The higher prevalence of *Culcita novaeguineae* in the deep slope areas could be somewhat due to its round shape, which could result in individuals rolling down the steep slopes to deeper areas if dislodged. Unlike most of the other echinoderms, the ophiuroid *Ophiothrix* spp. was observed only in the deep slope areas. Nearly all mollusks and the majority of arthropods were found predominantly in the shallow reef flat, shallow rubble slope, and shallow reef slope areas. Exceptions were the shrimp *Periclimenes tenuipes*, found along transects at all depths, and several unidentified hermit crab species also noted in deeper waters.

4.5 Rugosity

Rugosity measurements were taken along the first 10-m segment of each transect, corresponding to the *in-situ* coral census segments. Rugosity values ranged from less than 1.1 along several deep reef flat and deep slope transects to greater than 1.6 on many shallow reef slope survey lines (**Figure 13**). Along most of the transects, the rugosity reflected the roughness and complexity of the coral and rock/rubble substrate. However, there also were elevated rugosity levels along several transects with no exposed rock substrate, particularly within the deep reef flat areas, due to the presence of thick macroalgae and small burrows, cavities, and depressions in the sediments. Even along transects that were virtually flat, a rugosity of 1.05 or higher often was recorded. Along deep reef flat Transect 42, an elevated rugosity was reported due to the transect crossing over a mound of cement cinder blocks with no corals other than a solitary *Fungia* sp. reported along the transect.

While rugosity within the shallow reef flat and shallow rubble slope areas was relatively low, the rugosity along deep slope transects ranged from low to nearly as high as the shallow reef slope sites. Rugosity for each of the 72 transects is plotted against stony coral percent cover in **Figure 14**. Of the 16 transects with a coral percent cover >20%, all had rugosity values greater than 1.2 and 14 had rugosity >1.3. For the outboard higher-energy shallow reef slope sites, the high percent cover of coral corresponds to a high rugosity with an average rugosity of 1.61 for these five sites. This is also the case at Site 30, a lower-energy shallow reef slope site with a rugosity of 1.81, as well as at several of the deep slope sites with a high coral percent cover. However, the elevated rugosity values also were present at many locations with low coral cover, indicative of dead coral rock rubble, anthropogenic debris, heavy macroalgae cover, or irregular sediment surfaces.

The relationship between rugosity and coral cover was evaluated by calculating Spearman's rank correlation coefficient. The analysis was conducted for all habitats combined and each of the seven types of habitat or strata individually (**Table 12**). Coral cover and rugosity appeared to have significant correlation at Shallow Reef Flat sites, Outboard (higher-energy) Shallow Reef Slope sites, Deep Slope sites, and at all habitats combined.

Table 12. Spearman's Rank Correlation Coefficient for Rugosity versus Coral Cover

Habitat / Strata	Spearman's rank correlation coefficient	Probability
Shallow Reef Flat	0.88041	0.0206*
Outboard (higher-energy) Shallow Reef Slope	0.9	0.0374*
Inboard (lower-energy) Shallow Reef Slope	0.3	0.6238
Shallow Rubble Slope	0.71429	0.0713
Deep Reef Flat	0.40488	0.1344
Deep Slope	0.69524	<.0001*
Pinnacles	0.37048	0.3663
All Habitats Combined	0.72633	<.0001*

*Significant correlation

Figure 15 plots stony coral density and rugosity along the 10-m transects within each of the seven general habitats. For 13 of the 14 transects with a coral density of higher than 10 colonies per m², the rugosity exceeded 1.2, and on 11 of the transects it was higher than 1.3. Of the 9 transects with a coral density greater than 15 colonies per m², 7 had a rugosity greater than 1.3 and 5 greater than 1.4. This showed that areas of higher density coral abundance within the survey area have a corresponding higher rugosity. However, the elevated rugosity does not necessarily drive higher coral density as 18 transects with a coral density of less than 3 colonies per m² also had rugosities of higher than 1.1.

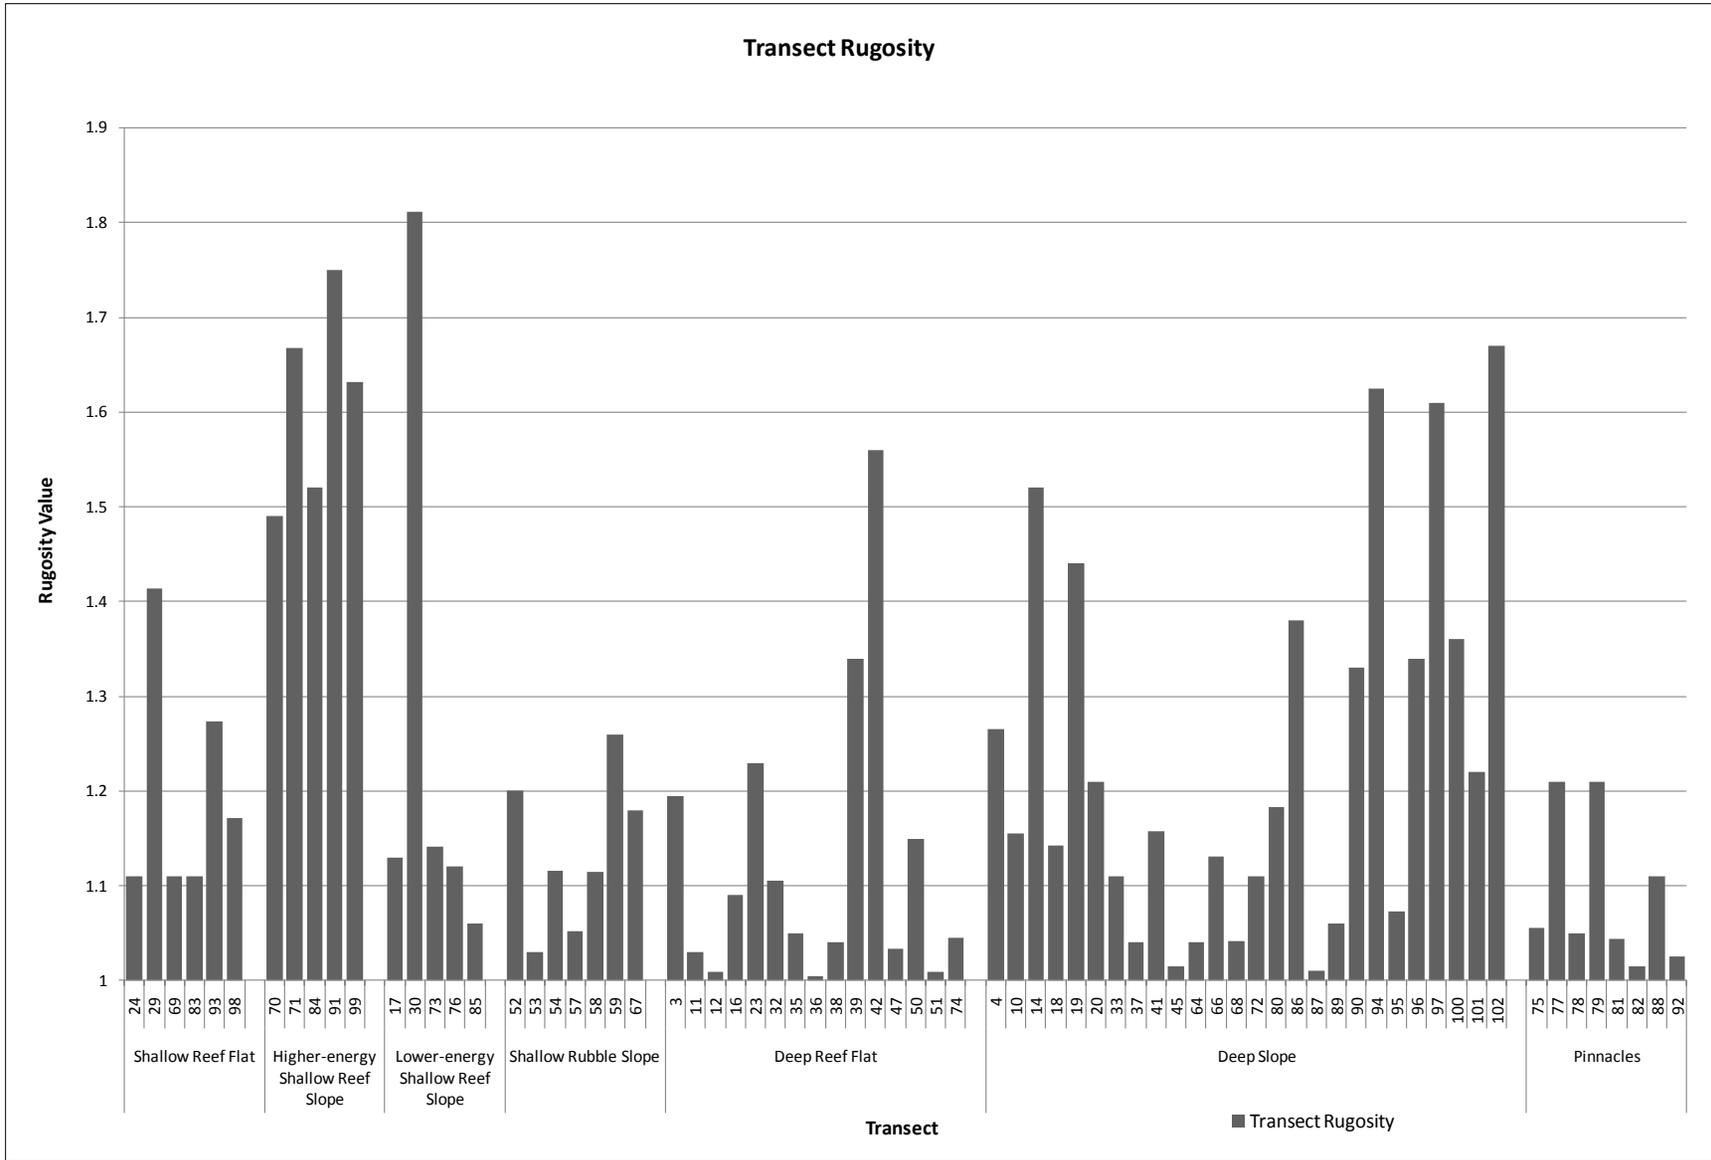

Figure 13. Rugosity Values Along the 10-m by 1-m *In-situ* Coral Survey Transects

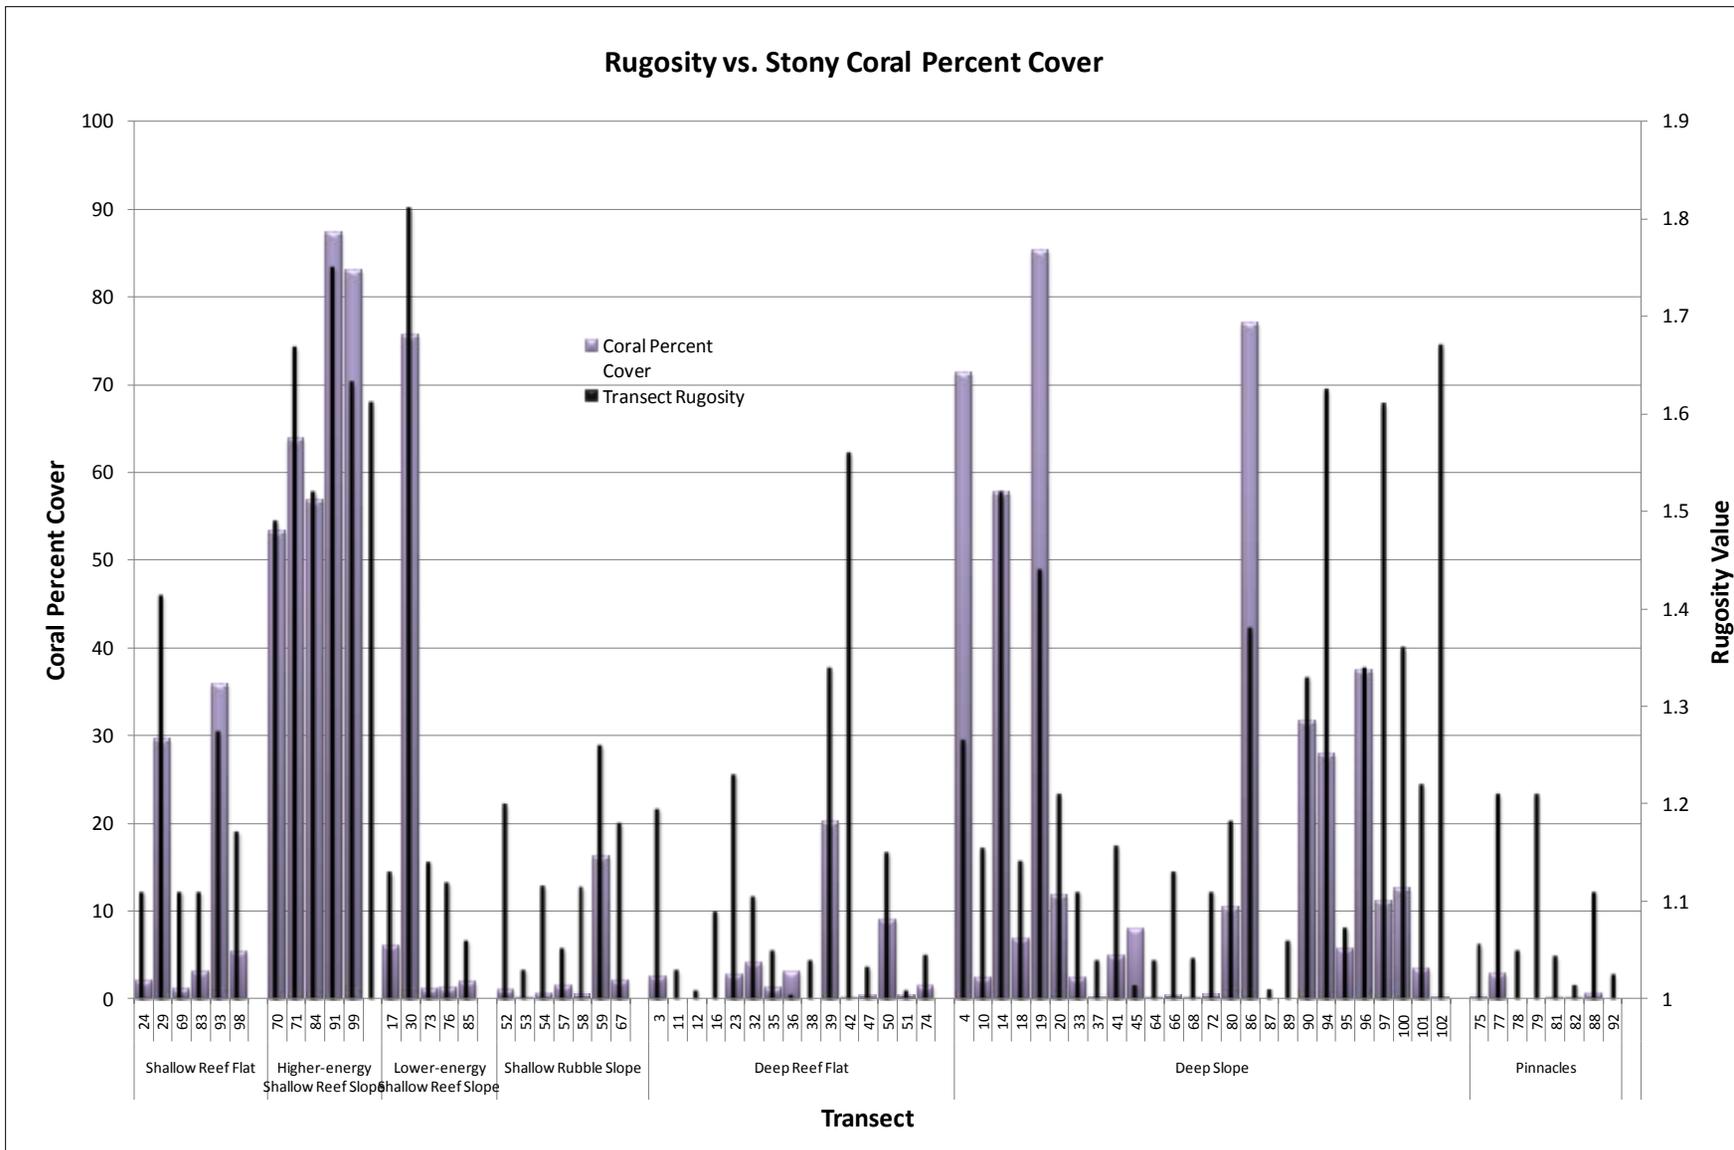

Figure 14. Rugosity Values Versus Stony Coral Percent Cover Along the 10-m by 1-m *In-situ* Coral Survey Transects

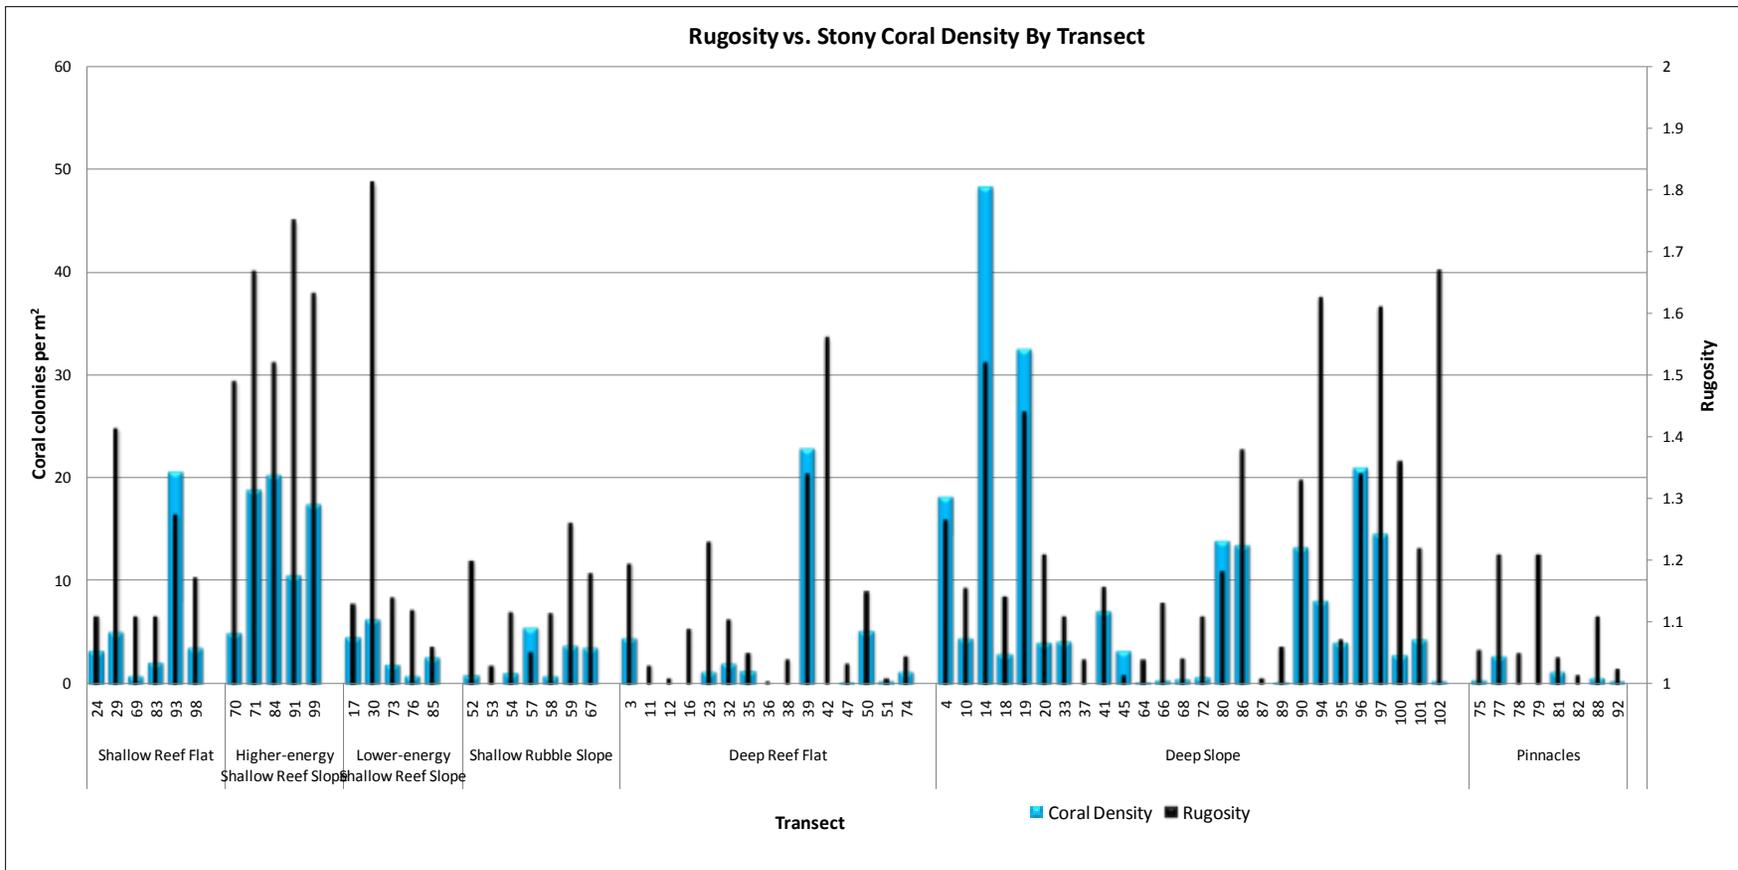

Figure 15. Rugosity Values Versus Stony Coral Density Along the 10-m by 1-m *In-situ* Coral Survey Transects

4.6 Incidental Sightings of Marine Mammals and Reptiles

No marine mammals were sighted within the harbor during the survey. On 8 November a hawksbill turtle was observed during a dive just south of Transect 17 (**Photo 7**). On 9 November a green turtle was observed both at the surface and by divers on the bottom at Transect 4. On 12 November a green turtle was observed several times on the surface about 100 m north of Transect 3. **Figure 16** shows locations of turtle sightings.

Photo 7. A hawksbill turtle (*Eretmochelys imbricata*) under an overhang of *Porites rus* near Site 17.

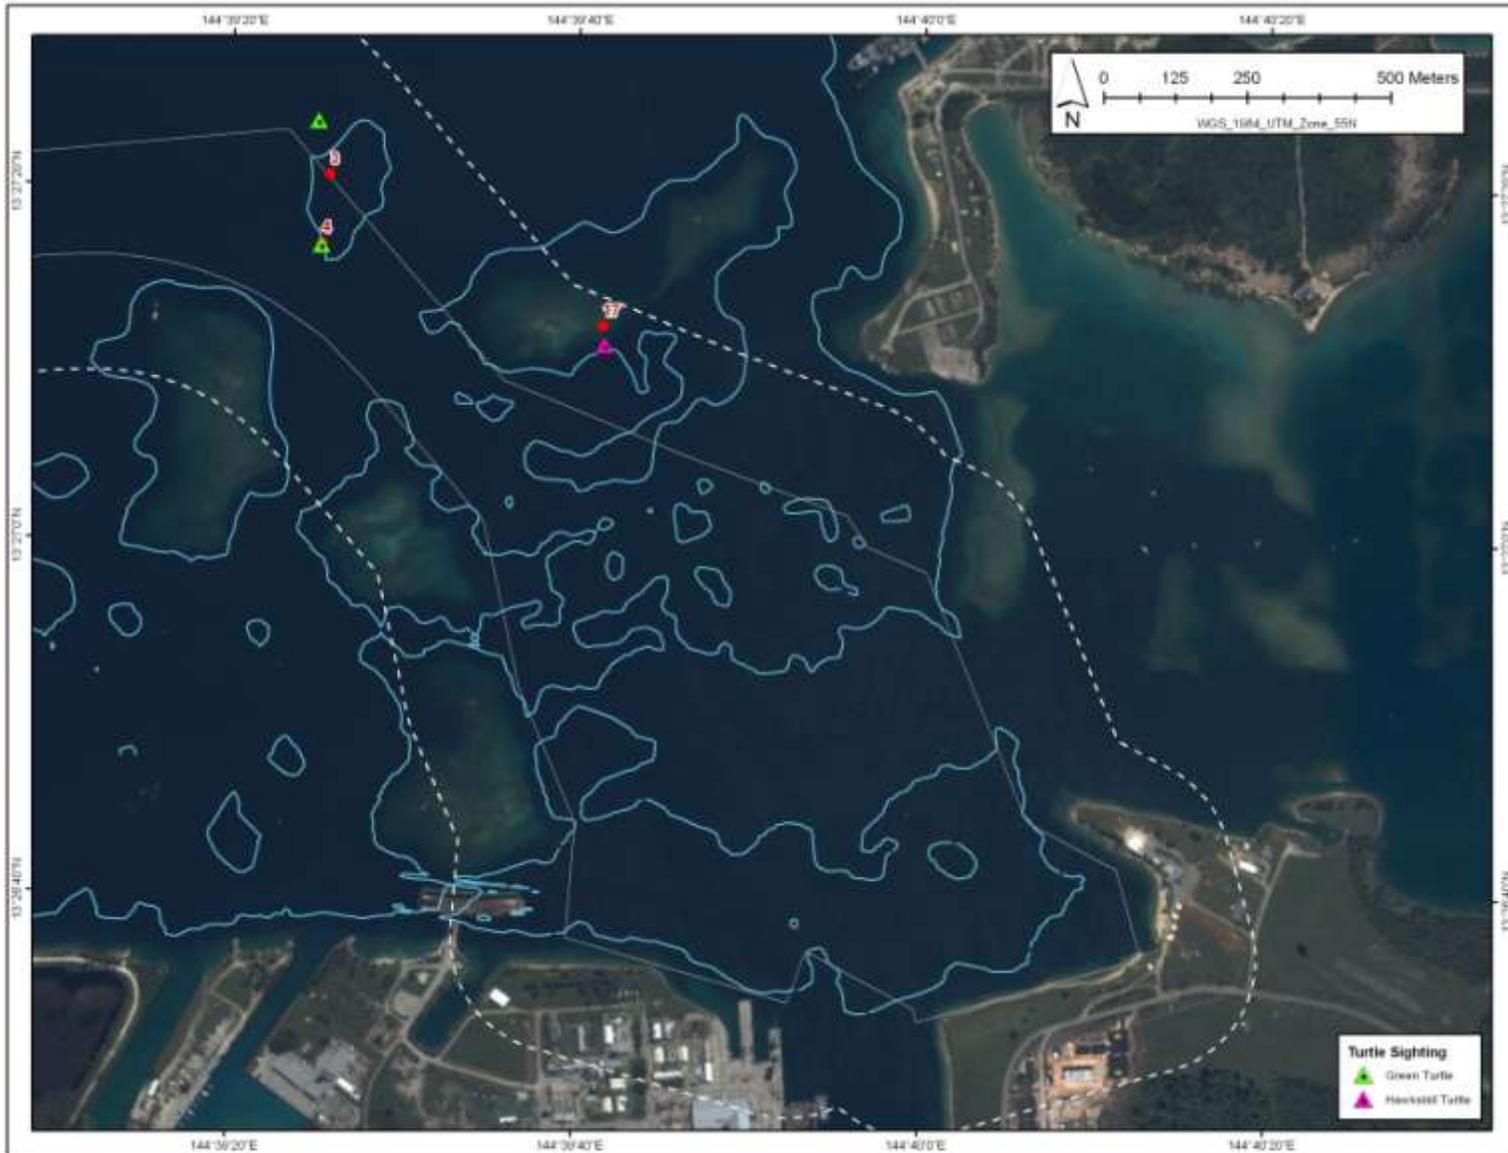

Figure 16. Locations of Turtle Sightings

5.0 DISCUSSION

These supplemental survey data add to the existing data collected by Dollar *et al.* (2009) and Minton *et al.* (2009) in attempting to provide a baseline assessment of the reef communities within the southeastern section of Apra Harbor, Guam. This survey served to fill in gaps in the data by utilizing *in-situ* quadrat sampling methods at the 37 remaining Dollar *et al.* sites not surveyed by Minton *et al.*, and by selecting and surveying 35 additional sites within and adjacent to the project area, including sites deeper than 60 ft within deep slope and pinnacles habitat.

As was noted in these previous studies, the benthic community within the harbor is highly variable and heterogeneous with a widespread and diverse macroalgae component along with well-developed coral reef habitat. This heterogeneity was apparent within all depth zones and habitats surveyed, with patches of high coral cover, dead coral rubble, bare sediments, and relatively thick macroalgae all possibly present along the same depth gradient on a single 25-m transect. In many cases deep slope transects seemed to cross only coral rubble or sandy-silt bottom while at depths a few feet greater or shallower, a fairly diverse or high percent cover coral or macroalgae area was observed. This variability within deep slope areas also was evidenced by the wide range of coral and macroalgae percent cover, with coral cover ranging from 0% to >85% and macroalgae cover from 1% to 88% along individual survey transects within this habitat.

Apra Harbor is a unique protected area less exposed to open ocean waves and swell than anywhere else on the island, and provides habitat for species less likely to thrive on the higher energy exposed reefs outside of the harbor. Corals, macroalgae and sponges within the harbor may therefore comprise a larger proportion of the benthic community than that observed in surrounding waters. From the 2009 surveys, Dollar *et al.* reported an overall algae percent cover of 40%, which was nearly two times that of the observed coral cover (22%). During this survey, average algae and coral percent cover was 33.8% and 14.5%, respectively. Both percent cover values were thus lower than those reported by Dollar *et al.* The lower algae percent cover could be partially due to sampling in different growth seasons, while the difference in coral cover may be attributable to many of the new supplemental survey transects or sites falling at water depths greater than 60 ft, with associated slightly lower coral percent cover.

Despite the greater depth of many of the sites studied during this supplemental survey, healthy living corals were found at water depths up to 90 ft along several of the deep slope transects within the harbor, indicating the corals have adapted to lower light levels and to at least some level of sedimentation. Due to minimal water movement at these water depths in the harbor, the corals are most likely shedding sediments through polyp and tentacular movement and active sloughing of sediment-laden mucus.

Identification of the Locations of the 35 New Survey Sites

Optimization of Survey Design Using Prospective Power Analysis

A.1 Background

In April and May 2009, Dollar et al. (2009) evaluated benthic community composition at 67 sites within the CVN project area using the photo-quadrat belt transect (PQBT) method. These 67 sites were located in relatively shallow waters (≤ 60 ft deep) and were separated into the following four “strata:”

- Direct¹ Flat – within proposed dredging footprint and $\leq 15^\circ$ incline;
- Direct Slope – within proposed dredging footprint and $> 15^\circ$ incline;
- Indirect¹ Flat – adjacent to proposed dredging footprint and $\leq 15^\circ$ incline; and
- Indirect Slope – adjacent to proposed dredging footprint and $> 15^\circ$ incline.

The efficacy of the PQBT method for determining benthic community composition was compared to that of the in-situ quadrat (ISQ) method by another concurrent study that was reported by Minton et al. (2009). During this study, comparative data were collected at 30 of the 67 transects surveyed by Dollar et al. (2009).

The Task 1 of the Work Execution Plan called for conducting coral reef community surveys at 37 (out of the original 67) sites that Minton et al., (2009) did not report on and an additional 35 sites, for a total of 72 sites.

Locations of the 37 sites had been previously determined by Dollar et al (2009). Initial guidance from the Navy to the survey team, received prior to the start of the field work, was that locations for the 35 new sites would be provided by the Resource Agencies (RA). Guidance received from the RAs, however, only contained general recommendations to be followed for selecting the additional survey sites. The Navy then redirected the survey team to identify locations for the 35 new survey sites based on the best available science and data while ensuring that the RAs recommendation were also considered.

According to guidance received from the RAs, “... *the ideal way to decide on how much additional effort to include in each stratum was to examine the variability of the data for each parameter of interest. Strata that have high variability would benefit from additional samples. Using the variability, it would be possible to calculate the optimal number of samples to add to a stratum to reduce the variability and improve the estimate. This should be done for each stratum*

¹ Note that from a coral reef habitat perspective direct and indirect are not true strata as they refer to arbitrary spatial delineations that do not have direct bearing on occurrence, diversity, or abundance of coral reefs.

using the existing the data and the current proposed level of sampling.²” This recommendation could not be implemented because the only existing data the survey team had access to at the time were the summary data contained in the Dollar et al., (2009) and Minton et al., (2010) reports. Severe time constraints precluded acquisition and detailed analyses of raw data that would be required to implement this recommendation.

Other RA recommendations (also provided in the communication identified in footnote 2) included the following:

- Some of the additional 35 sites be placed at shallower depths where more corals reside.
- The new sites cover the following six strata:
 - Shallow reef flats (SRF)
 - Deep reef flats (DRF)
 - Windward shallow reef slopes (WSS)
 - Leeward shallow reef slopes (LSS)
 - Deep slopes (DS)
 - Northernmost pinnacles (NMP)

During an impromptu field meeting that was held at Naval Base in Guam on Nov 6, 2010 towards the end of the coral survey field training session, Mr. Gerry Davis³ recommended that a more rigorous statistical approach such as a power analyses should be considered in setting up a survey design⁴.

The final two considerations in the site selection process were as follows:

- It is a known and documented fact that coral abundance and site homogeneity/heterogeneity vary among the different strata and that more corals typically reside at shallower depths as compared to deeper areas.
- Since all sites surveyed in 2009 were located in relatively shallow depths (<60 ft), it was acknowledged by both the Navy and RAs (see footnote 2) that additional sites were needed in deeper areas to ensure that all depths were adequately surveyed.

² From the document entitled “*Comments on Sampling Design Section of the WEP (pages 1-4)*,” Attachment to Mr. Mr. Davis’ e-mail to JT Hesse (NAVFAC PAC) and HDR Staff dated Nov 9, 2010.

³ Assistant Regional Administrator for Habitat Conservation Division, National Marine Fisheries Service, National Oceanic and Atmospheric Administration.

⁴ A proposal and work plan for conducting the suggested power analysis using available data from Dollar et al. (2009) and Minton et al. (2010) was forwarded to Mr. Davis on Nov 7, 2010 via the NTR. Results and recommendations from the analyses were discussed with Mr. Davis at a meeting held at the Guam Hilton on the evening of Nov 8, 2010.

A.2 Identification of the Locations of 35 New Survey Sites

A three-step process was followed to optimize the survey design and distribute the 35 new sites between the six strata recommended by the RAs, namely shallow reef flats, deep reef flats, windward shallow reef slopes, leeward shallow reef slopes, deep slopes, and northernmost pinnacles.

- Step 1 – Determine the optimum number of sites to be surveyed in shallow (<60 ft) vs. deeper (>60 ft) areas.
- Step 2 – From Step 1, take the optimum number of survey sites determined for shallow areas and distribute them among reef flats, windward slopes, leeward slopes, and northernmost pinnacles that occur at depths of <60 ft.
- Step 3 – From Step 1, take the optimum number of survey sites determined for deeper areas and distribute them among reef flats, windward slopes, leeward slopes, and northernmost pinnacles that occur at depths of >60 ft.

A.2.1 Step 1

As recommended by the RAs, a prospective power analysis (proc GLMPOWER, SAS 9.2) was performed using existing data to determine the optimum distribution of survey effort between shallow and deep strata. Statistical power is the probability of successfully rejecting the null hypothesis (H_0), i.e. not accepting the H_0 when it is false. In this case the H_0 was that there was *no difference* in mean coral abundance, as measured by point counts, between shallow and deeper areas. The alternate hypothesis (H_A) was that there *were* differences between the two depths.

A power level of 0.80⁵, for example, for a given distribution of sites between shallow and deeper waters (say, a 3:1 ratio), would indicate that there is an 80% probability that the test would accurately detect differences between the two depths when the difference actually exists. In other words, if the survey sites were to be distributed between shallow and deeper waters in a 3:1 ratio, a power level of 0.80 for this distribution ratio would mean that there is at least an 80% chance of successfully rejecting H_0 (survey design *would not be able to detect differences* in mean coral abundance between the two depths that are actually different) and accepting H_A (survey design *would be able to detect* differences in mean coral abundance between the two depths that are actually different).

Two different weighting ratios (shallow vs. deep) were tested: 1.5 to 1, and 2 to 1. These ratios were considered a reasonable compromise between the fact that corals are known to be more

⁵ A power level of 0.80 is commonly assumed to provide sufficient chance of rejecting H_0 when it is false (Cohen 1992).

abundant at shallower depths than deeper areas and the acknowledgment that additional deep water sites need to be surveyed.

Dollar et al. (2009) had previously reported point counts for the 67 sites surveyed in 2009⁶. These data were used to determine mean point counts for the four strata represented by the 67 sites, namely direct flat, direct slope, indirect flat, and indirect slope (**Table A1**).

Table A1: Means Coral Abundance for 4 Strata Surveyed in 2009

(From: Dollar et al. (2009))

Stratum	Mean Point Count
Direct Flat	106.95
Direct Slope	101.17
Indirect Flat	186.08
Indirect Slope	278.07

Mean point counts between direct flat and direct slope were very similar, indicating that coral abundance between these two strata, at least as measured by mean point counts, was not radically different. It has been previously established that when little quantifiable difference exists between populations, as indicated by similar means for example, the ability to distinguish between the two populations is greatly diminished (Brosi and Biber, 2009; Cohen, 1992).

Mean point counts between indirect flat and indirect slope however differed considerably (186.08 and 278.07, respectively) and were therefore judged suitable for use in distinguishing between the two data sets using tests such as a GLM POWER procedure. For this analysis, it was assumed that the indirect flat and indirect slope point count data sets were normally distributed and generally confirmed to the *hypothetical* distribution shown in **Figure A1**.

The six strata recommended by the RAs were accordingly assigned mean values as follows:

- Shallow reef flats and deep reef flats were assigned projected means of 186.08 based on the existing mean point count for indirect flat areas.
- Sloping and pinnacle strata (windward shallow reef slopes, leeward shallow reef slopes, deep slopes and northern-most pinnacle) were assigned projected means based on existing data for indirect sloping areas (**Table A2**).

Variation in point count within each of the six strata was accounted for by conjecturing a range of reasonable standard deviation values (75 - 250), based on existing estimates (SAS Inst., 2008).

⁶As indicated previously, at the time the analysis was conducted, raw data were not available and due to severe time constraints the team had to rely on the summary data presented in the Dollar et al. (2009) report.

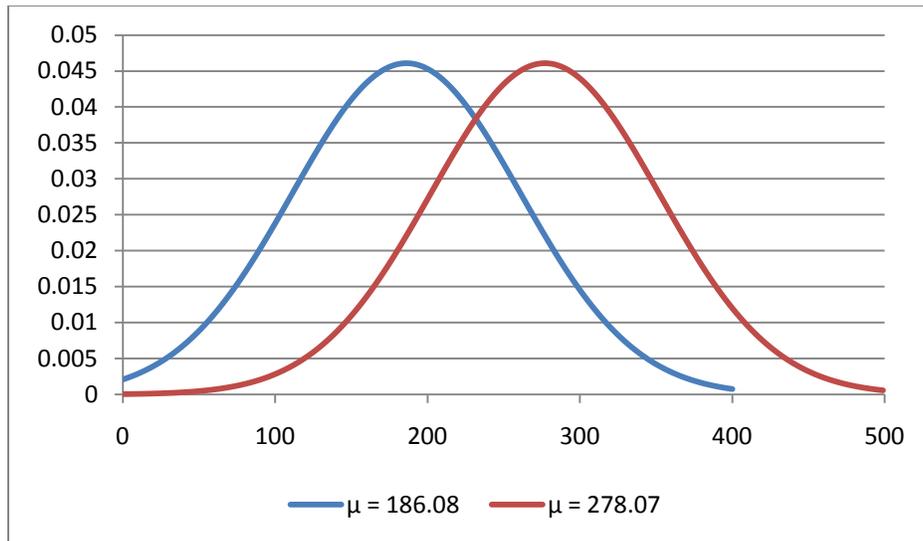

Figure A1: Assumed Hypothetical Distribution of Point Count Data Within Indirect Flat and Indirect Slope Strata
(sample standard deviation used is 75)

Table A2: Assigned Projected Means for the Six Strata Recommended by the RAs
(Extrapolated values based on Dollar et al. (2009))

Strata	Estimated Mean Point Count
SRF	186.08
DRF	186.08
WSS	278.07
LSS	278.07
DS	278.07
NMP	278.07

Using proc GLMPOWER in SAS v. 9.2, a power analysis was constructed by providing values for the total number of sampling sites, number of strata, expected sample means within each stratum, standard deviation ranges, and desired alpha values (significance level). The classification variables were identified as strata, and the parameter of interest was identified as coral abundance, as measured by mean point count. The results of the power analysis were used as a guide for distributing survey sites between various strata, in a manner that optimized the survey effort and maximized the probability that difference among the various strata, where they actually existed, would be detected.

A.2.1.1 Step 1 Results

For a total sample size of 72, a 2:1 ratio (shallow to deep) and an error standard deviation of 75, the GLMPOWER procedure returned a power of 0.955, with an alpha value of 0.05 (**Figure**

A2). This meant that if the survey sites were to be distributed between shallow and deeper waters in a 2:1 ratio, there would a 95% chance of successfully rejecting H_0 (survey design *would not be able to detect differences* in mean coral abundance between the two depths that are actually different) and accepting H_A (survey design *would be able to detect* differences in mean coral abundance between the two depths that are actually different).

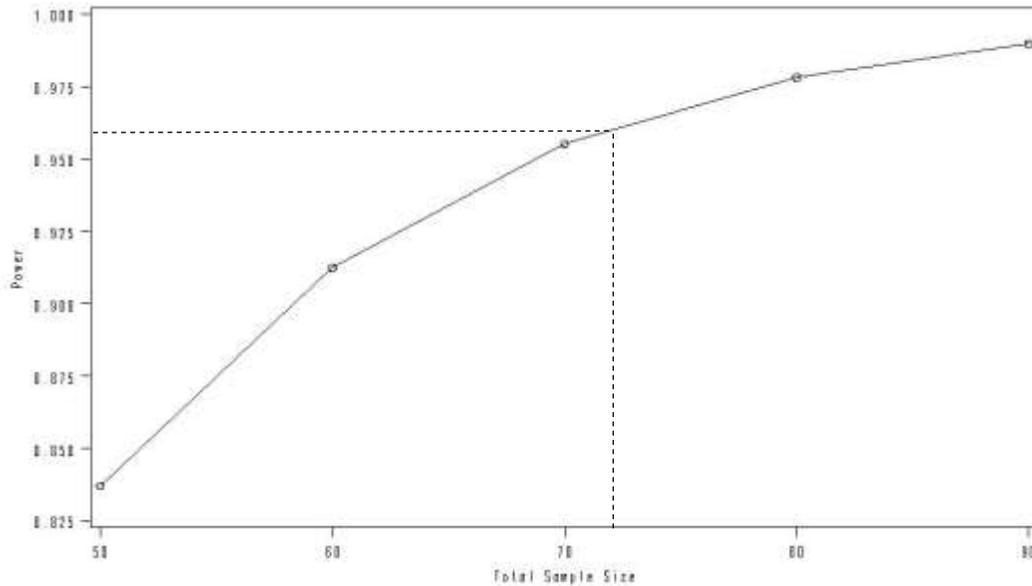

Figure A2: Power Analyses Output Graph

Guided by the results of the power analysis, the 2:1 ratio was used to distribute 72 survey locations between the six strata as shown in **Table 3**.

Table 3: Suggested Distribution of the 72 Survey Sites between RA Recommended Strata

Strata	Proposed number of Survey Points
SRF [@]	14+2
DRF	7
WSS	14
LSS	14
DS	7
NMP	14
Total	72

[@] 2 extra sites were assigned to this stratum based on best professional judgment since corals are more likely to be found in this stratum as compared to the other five.

A.2.2 Steps 2 and 3

Locations of 37 survey sites had been previously determined by Dollar et al. in 2009. In order to distribute the 35 new survey sites between the six strata such that the total number of sites per

stratum would add up to the suggested distribution in **Table 3**, summary data from the Dollar et al. (2009) report were analyzed.

Based on a review of the Dollar et al. (2009) summary data and using best professional judgment the previously located 37 sites were assigned to one of the six strata. The new sites were then added to each stratum, such that the total number of sites per stratum roughly corresponded to suggested total per stratum shown in **Table 3**.

The suggested distribution of the 35 new sites between the six strata is shown in **Table 4**.

Table 4: Suggested Distribution of 35 New Survey Sites between RA Recommended Strata

Strata	Number of Sites

LSS	3
DS	14
NMP	8
Total	35

A.3 Post Survey Analyses

After the surveys were completed raw data from the Dollar et al. (2009) study were obtained and further evaluated (**Figures A3 and A4**).

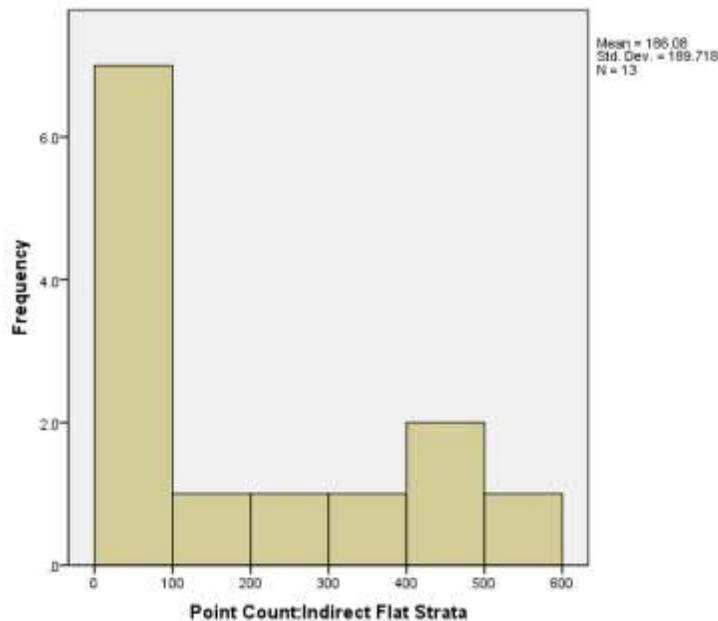

Figure A3: Indirect Flat Strata Point Counts Frequency Distribution

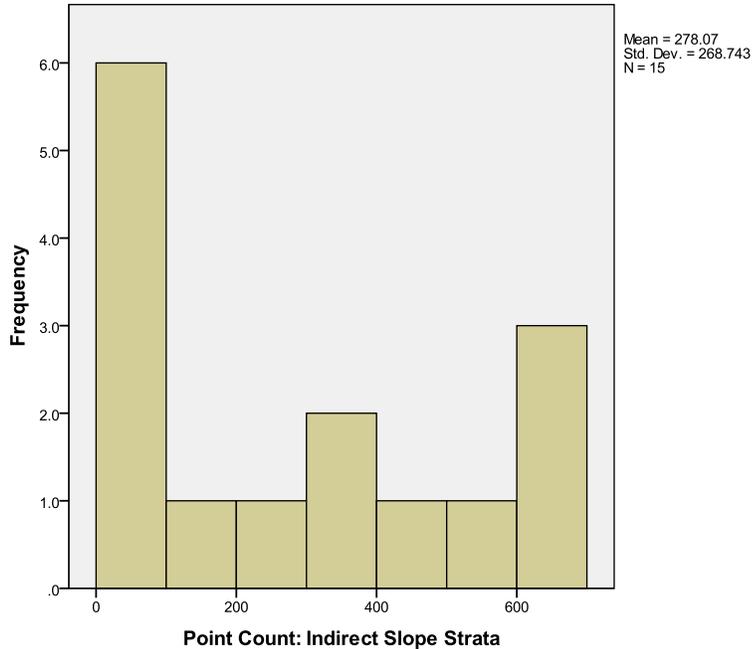

Figure A4: Indirect Slope Strata Point Counts Frequency Distribution

The plots in **Figures A3** and **A4** do not depict the data as being normally distributed, and therefore the pre-survey assumption that coral abundance data are normally distributed is not supported.

The “Fitting Distributions” procedure within SYSTAT 11 (SYSTAT Inc., 2004) was used to try and fit an appropriate statistical distribution to the raw data from Dollar et al. (2009) study. Distribution types included were 18 Continuous distributions types (Beta, Cauchy, Chi-square, Exponential, Gamma, Gompertz, Gumbel, Laplace, Logistic, Logit, Lognormal, Normal, Pareto, Rayleigh, Triangular, Uniform, Wald, Weibull) and 2 discrete distribution types (Negative Binomial and Poisson). Also, to test the goodness-of-fit to a proposed distribution, a one-sample Kolmogorov-Smirnov test was used.

The (raw data derived) empirical distribution was compared to the hypothesized distribution function. The test statistic is based on the maximum absolute difference between the two functions. A probability value ≤ 0.05 indicates a significant departure from the proposed function, i.e., the distribution is not of the specified type. A value > 0.05 indicates that there is no basis, based on the given sample, for rejecting the hypothesis that the empirical data are from the proposed distribution type. This does not mean the distribution is of the hypothesized type, only that there is insufficient evidence to say that it is not.

Test results (**Table 5**) indicate that, in nearly all cases, the empirical distribution type was significantly different than the proposed distribution. Only in case of flat strata were the Gumbel and Logistic distributions not rejected. Even in those cases, the probability levels were near the 0.05 value. Additionally, neither of these distributions was > 0.05 for the Slopes transects.

Concordance between the two transect types would have helped to strengthen the conclusion. Because no clearly defined distribution type is apparent, it is recommended that all subsequent hypothesis tests involving these data be conducted using non-parametric statistical procedures.

Table 5: Dollar et al. (2009) Raw Data Distribution Testing

Distribution Tested	Parameter	
	Flat	Slope
Beta	NA	NA
Cauchy	0.0003 **	≤0.0001 **
Chi-square	≤0.0001 **	≤0.0001 **
Exponential	0.0158 *	≤0.0001 **
Gamma	NA	NA
Gompertz	NA	NA
Gumbel	0.1165	0.0188 *
Laplace	0.0030 **	≤0.0001 **
Logistic	0.0696	0.0055 **
Logit	NA	NA
Lognormal	NA	NA
Negative Binomial	≤0.0001 **	≤0.0001 **
Normal	0.0006 **	≤0.0001 **
Pareto	NA	NA
Poisson	≤0.0001 **	≤0.0001 **
Rayleigh	NA	NA
Triangular	NA	NA
Uniform	≤0.0001 **	≤0.0001 **
Wald	NA	NA
Weibull	NA	NA

Additional analysis of the raw data may provide a more comprehensive understanding of underlying skew and/or kurtosis of the data. The use of other variables, including percent cover data, species richness, diversity, evenness might also be explored. Once the behavior of the raw data is better understood, various approaches to further analysis might be undertaken, such as normalization of the data (e.g. via logarithmic transformation) to allow the application of parametric statistical analyses, or the application of appropriate non-parametric analyses.

Biosketches of Key Survey Personnel

Survey Personnel	Organization	Function
Keith D. Spring	CSA International, Inc.	Lead Marine Scientist
Dr. Steven L. Coles	Bishop Museum, Hawaii	Coral Expert
Dr. Yimnang Golbuu	Palau International National Coral Reef Center	Coral Expert
Dr. Douglas Fenner	Department of Marine & Wildlife Resources, American Samoa	Coral Expert
Victor Bonito	Reef Explorer, Fiji	Coral Expert
David Snyder	CSA International, Inc.	Marine Scientist
Jeffery Landgraf	CSA International, Inc.	Marine Scientist
Dr. Matthew Lybolt	CSA International, Inc.	Marine Scientist
Katie Laing	AECOS, Inc., Hawaii	Marine Scientist
Stacey Kilarski	AECOS, Inc., Hawaii	Marine Scientist
Louise Giuseffi	Independent	Marine Scientist
Tony Wadley	CSA International, Inc.	Dive Supervisor
Dustin Myers	CSA International, Inc.	Dive Supervisor

Mr. Keith D. Spring – Senior Scientist, CSA International, Inc.

Mr. Spring is a marine biologist with over 30 years oceanographic and environmental science experience. He is the Director of the Coastal and Ocean Sciences Division at CSA International, Inc. and has served as a Project Manager and/or Chief Scientist on more than 200 oceanographic studies, including multidisciplinary baseline studies, environmental monitoring programs, nearshore hard bottom and reef characterization surveys, habitat damage assessment surveys, and photodocumentation surveys. Monitoring programs have included beach nourishment projects, ship channel and harbor dredging projects, ocean dredged material disposal sites, reefs impacted by ship groundings, offshore oil and gas drilling, and wastewater outfalls. Mr. Spring has extensive experience as a scientific diver, performing more than 2,000 dives in the past 30 years. He has directed or participated in biological surveys of nearshore and offshore reefs, seagrass beds, and soft bottom habitats in connection with beach and reef restoration and dredging projects on both the east and west coasts of Florida, in the Bahamas, Puerto Rico, United Arab Emirates, Qatar, Hawaii, and Guam. He has a Master of Science in Biological Oceanography, Florida Institute of Technology, 1981; and a Bachelor of Science in Biological Sciences, S.U.N.Y. at Brockport, 1976.

Dr. Steven L. Coles – Marine Invertebrate Zoologist, Bishop Museum, Hawaii

Dr. Coles is presently an invertebrate zoologist in the Department of Natural Sciences at Bishop Museum, Honolulu, Hawaii, and manager of research projects to determine the composition of the biological communities and the impact of introduced species on the native biota of harbors on the islands of Hawaii, including Pearl and Honolulu Harbors, Kaho'olawe Island, and Midway and Johnston Atolls. He is also an affiliate faculty member at the Hawai'i Institute of Marine Biology, University of Hawai'i. The author of numerous papers on corals his research interests include the ecology of marine species invasions, the ecology and biogeography of reef corals and symbionts, the effects of natural and pollution stresses on corals and coral reefs, the environmental factors inducing coral bleaching, and marine communities in high latitude coral

reef systems. He has done field and survey work in the mainland USA, Bahamas, Bermuda, Hawaiian Islands and Johnston Atoll, Palau, Fiji, Marshall Islands, American Samoa, the Arabian Gulf, and the Gulf of Oman. He has a Ph. D. in Zoology, University of Hawaii; an M.S. in Zoology, University of Georgia; and a B. A. in Biology, Dartmouth College.

Dr. Yimnang Golbuu – Palau International Coral Reef Center

Dr. Golbuu is currently the Chief Researcher at the PICRC. He has over 12 years of research experience and has mentored and supervised numerous researchers, research assistants and students. He has been a Principal Investigator, Co-Principal Investigator and Collaborator on grants from numerous sources including the Packard Foundation, NOAA, EPA, National Fish and Wildlife Foundation, UNESCO, and National Science Foundation. Dr. Golbuu has published his research work in numerous peer-reviewed journals as well as book chapters and presented them in international scientific meetings. Besides his work in Palau, he has conducted coral reef research and trainings in other islands of Micronesia including Yap, Guam and Pohnpei. His degrees include: Ph.D., School of Environmental Science and Management, Southern Cross University, Australia; Master of Science, Biology, University of Guam; and Bachelor of Science, Biological Sciences, University of California-Davis.

Dr. Douglas Fenner – Coral Reef Monitoring Ecologist, Department of Marine and Wildlife Resources, American Samoa

Dr. Fenner is currently serving as a coral reef ecologist in American Samoa. He is author of numerous scientific publications including the book *Corals of Hawaii*. For six years he worked for the world's top coral taxonomist, Dr. "Charlie" Veron at the Australian Institute of Marine Science. Dr. Fenner named and described seven new species of coral with Dr. Veron. He was a co-author on the Science paper that provided the first evaluation ever of the endangered species status of all the world's reef corals, which reported that one third had heightened levels of risk of extinction. He discovered the first annual summer mass coral bleaching known in the world. He has also written a review of the removal of large reef fish from most of the world's reefs by overfishing. Information he gathered on the rarity and overfishing of the 10 largest reef fish species in American Samoa resulted in American Samoa becoming the first place in the world to promise to protect all of its largest reef fish. A certified NOAA Scientific Diver, he has done field work in Puget Sound, the Caribbean, Hawaii, American Samoa, Philippines, Italy, Australia, Indonesia, Papua New Guinea, Malaysia, Andaman Islands, Rodrigues Island, Fiji, Madagascar, New Caledonia, Lord Howe Island, Tasmania, and Florida. His degrees include a Ph.D. in Psychology (Animal Learning & Behavior), University of Pennsylvania, and a B.A. in Biology, Reed College.

Mr. Victor Bonito – Director of Reef Explorer, Fiji

Mr. Bonito currently serves as director and head scientist for Reef Explorer in Fiji working to improve local knowledge of marine ecology and conservation, conduct research for management planning and evaluation, and assist in the development of sustainable livelihood opportunities. He previously served as an invertebrate specialist for NOAA, conducting quantitative and qualitative marine invertebrate surveys at Wake Atoll, U.S. Pacific Islands. He also spent three years in Guam conducting island-wide biodiversity surveys, establishing a baseline ecological monitoring programs for Haputo Ecological Reserve, and conducting a detailed coral community survey of Tanguisson Reef. Over the last 10 years, Victor has conducted field work on reefs in

the USVI, Belize, FL. Keys, main HI islands, American Samoa, Madagascar, Micronesia (Palau, Yap, Saipan, Guam), and SE-Asia (Indonesia, Singapore, Malaysia, Thailand) as well as Fiji. His degrees include Master's of Science in Biology, University of Guam Marine Laboratory; and Bachelor's of Science in Biology, University of North Carolina.

Ms. Katie Laing – Marine Biologist, AECOS, Inc., Hawaii

Ms. Laing has held positions including Marine Biologist, Safety Diver, Water Quality Specialist, College Oceanography Instructor, and Microbiologist. She has managed and performed assessments ranging from reconnaissance surveys for Environmental Assessments to complex quantitative coral reef surveys for Environmental Impact Statements and to meet permit requirements. These assessments have covered a wide variety of projects including: hard and soft bottom dredging, groin construction, beach nourishment, zone-of-mixing, in-water construction, underground pipeline placement, and large coastal developments. She has prepared essential fish habitat assessments, habitat equivalency analyses, long term biological and water quality monitoring plans, and compensatory mitigation plans. Katie has conducted surveys for *AECOS* on Oahu, Kauai, Maui, Hawaii, Molokai, and Guam. Survey locations have included: near shore coral reefs, sand beaches, small boat harbors, large commercial harbors, embayments, and rocky intertidal areas. Her degrees include Master's of Science in Marine Biology, and Bachelor's of Science in Biology, University of North Carolina - Wilmington.

Ms. Louise Giuseffi – Marine Biologist, Hawaii

As a marine algal specialist for the University of Hawaii she has identified Pacific algal species from American Samoa, Hawai'i, Guam and Saipan; and prepared herbarium specimens and slides. Ms. Giuseffi has served on research cruises for NOAA/PIFSC Coral Reef Ecosystems Division. These cruise efforts included reconnaissance surveys and removal of derelict fishing gear to mitigate threats to the coral reef ecosystems and endangered animals in the Papahānaumokuākea Marine National Monument, analyzing and classifying optical imagery from digital videos from towed underwater camera systems, and processing multi-beam bathymetric data. She has a Bachelor of Science in Biology, University of Hawaii.

Photo D-6. The sponge *Clathria eurypa* at a shallow reef flat site.

Photo D-7. The sponge species *Haliclona turquoisia* growing among colonies of *Porites rus*.

Photo D-8. A small individual of the sponge species *Ianthella basta* growing out from a colony of the stony coral *Lobophyllia corymbosa*.

Photo D-9. The sponge *Iotrochota ditrochota* on an expanse of *Porites rus*.

Photo D-10. The sponge *Liosina granularis* at a shallow reef flat site.

Photo D-11. The sponge *Stylissa massa* growing in an area of heavy *Porites rus* cover.

Photo D-12. The encrusting sponge *Xestospongia carbonaria* growing over *Porites rus* colonies.

Photo D-13. A colony of the stony coral *Galaxea astreata* with the green alga *Halimeda* sp.

Photo D-14. The coral species *Pectinia ~albicornis*.

Photo D-15. The solitary coral *Fungia* sp.1, a possibly undescribed species.

Photo D-16. The solitary coral *Fungia* sp. 2, a possibly undescribed species.

Photo D-17. A colony of the stony coral *Porites* sp. 2, a possibly undescribed species.

Photo D-18. A colony of the stony coral *Montipora* sp. 3, a possibly undescribed species.

Photo D-19. A colony of the stony coral *Montipora* sp. 7, a possibly undescribed species.

Photo D-20. The stony coral *Acropora granulosa*, a relatively rare species outside of the harbor.

Photo D-21. Large colonies of the tabulate stony coral *Acropora latistella*, relatively rare outside of the harbor.

Photo D-22. The stony coral *Lobophyllia hataii*, also relatively rare outside of the harbor.

Genus Species	%Cover	Color	Description
Caulerpa filicoides	1		
Caulerpa verticillata	6		
Cyanobacteria	1		
Halimeda sp.	2		fan-shaped
Halimeda velazquesii	15		
Ralfsia ? sp.	10		
Tydemania expeditionis	1		
Unidentified crustose coralline	40		
Rhopalaea sp.	1		
Unid. bryozoa	1	beige	encrusting
Porites rus	20		
Xestospongia aff. carbonaria	2		
	4		rock, Halimeda hash
Caulerpa filicoides	2		
Caulerpa serrulata	1		
Caulerpa verticillata	20		
Dictyopteris repens	2		
Dictyota sp.	2		
Halimeda sp.	12		
Ralfsia ? sp.	4		
Unidentified crustose coralline	15		
Rhopalaea sp.	1		
Montipora sp.	1		
Pocillopora damicornis	1		
Porites rus	12		
Xestospongia aff. carbonaria	4		
	25		rock, Halimeda hash
Caulerpa filicoides	1		
Caulerpa verticillata	2		
Cyanobacteria	6		
Dictyopteris repens	5		
Dictyota adnata	1		
Halimeda velazquesii	30		
Mesophyllum ? sp.	1	red	large, plates, under ledges
Ralfsia ? sp.	10		
Tydemania expeditionis	1		
Unidentified crustose coralline	25		
Polycarpa sp.	1		
Unid. bryozoa	2		
Porites rus	20		
Stylocoeniella sp.	1		
Xestospongia aff. carbonaria	1		
	2		
Caulerpa verticillata	1		
Cyanobacteria	3		
Dictyopteris repens	2		

Dictyota sp.	15		
Halimeda sp.	12		
Peyssonnelia ? sp.	1	red	large, plates, under ledges
Ralfsia ? sp.	3		
Tydemania expeditionis	1		
Unidentified crustose coralline	25		
Pocillopora damicornis	1		
Porites rus	17		
Plakina sp. 1	1		
	25		rock, Halimeda hash
Caulerpa filicoides	1		
Caulerpa verticillata	1		
Cyanobacteria	1		
Dictyopteris repens	8		
Dictyota adnata	1		
Halimeda velazquesii	10		
Ralfsia ? sp.	15		
Tydemania expeditionis	1		
Unidentified crustose coralline	20		
Phallusia julinea	1		
Unid. bryozoa	1		
Porites rus	45		
Xestospongia aff. carbonaria	1		
Caulerpa filicoides	1		
Dictyopteris repens	13		
Dictyota sp.	13		
Halimeda sp.	45		
Peyssonnelia ? sp.	1		large, plates, under ledges
Ralfsia ? sp.	8		
Unidentified crustose coralline	5		
Ascidea sp.	1		
Rhopalaea sp.	1		
Porites rus	6		
Stylocoeniella sp.	1		
Plakina sp. 1	1		
Stylissa massa	1		
	8		rock, Halimeda hash
Dictyopteris repens	5		
Dictyota adnata	7		
Halimeda velazquesii	15		
Mesophyllum ? sp.	2	red	large, plates, under ledges
Ralfsia ? sp.	15		
Unidentified crustose coralline	20		
Unid. bryozoa	2		
Porites rus	25		
Plakina sp. 1	1		
Pseudoceratina sp. 1	1		

Stylinos ruetzleri	1		
Xestospongia aff. carbonaria	1		
	4		
Caulerpa filicoides	1		
Dictyopteris repens	2		
Dictyota sp.	10		
Halimeda sp.	35		
Ralfsia ? sp.	2		
Unidentified crustose coralline	24		
Rhopalaea sp.	1		
Porites rus	24		
Stylissa massa	1		
Unid. sponge	1		boring
	2		rock, Halimeda hash
Cyanobacteria	2		
Dictyota adnata	3		
Dictyota ? ceylanica	1		<1mm width
Halimeda velazquesii	15		
Mesophyllum ? sp.	3	red	large, plates, under ledges
Ralfsia ? sp.	25		
Unidentified crustose coralline	20		
Unid. bryozoa	2		
Porites rus	25		
Stylissa massa	1		
Unid. sponge	1	brown	hard, large oscules on top
Xestospongia aff. carbonaria	1		
	3		
Caulerpa filicoides	1		
Cyanobacteria	2		
Dictyopteris repens	10		
Dictyota sp.	4		
Halimeda sp.	25		
Peyssonnelia ? sp.	1		large, plates, under ledges
Ralfsia ? sp.	8		
Unidentified crustose coralline	12		
Porites rus	36		
	2		rock, Halimeda hash
Amphiroa sp.	1		
Dictyopteris repens	1		
Halimeda sp.	2		small
Unidentified crustose coralline	1		crustose coralline
Unidentified sp.	3		Ralfsia-like
Ventricaria ventricosa	1		
Polycarpa sp.	1		
Porites rus	93		
Tedania meandrica	1		
Amphiroa sp.	2		

Dictyopteris repens	1		
Unidentified crustose coralline	3		crustose coralline
Phallusia julinea	1		
Porites rus	90		
Spirobranchus giganteus	1		
Plakina sp.	1		
Rhabdastrella globostellata	2		
Stylinos ruetzleri	1		
Xestospongia aff. carbonaria	1		
	2		hard bottom
Cyanobacteria	1		
Dictyopteris repens	1		
Halimeda sp.	4		elongate
Unidentified crustose coralline	2		crustose coralline
Unidentified sp.	2		Ralfsia-like
Porites rus	88		
Tedania meandrica	1		
Xestospongia aff. carbonaria	1		
	4		hard bottom
Amphiroa sp.	1		
Dictyopteris repens	1		
Halimeda sp.	8		small
Tydemania expeditionis	1		
Unidentified crustose coralline	2		crustose coralline
Unidentified sp.	1		Ralfsia-like
Porites rus	85		
Spirobranchus giganteus	1		
Unid. sponge	1	red	Clathria-like
	2		hard bottom
Cyanobacteria	1		
Dictyopteris repens	3		
Halimeda sp.	3		small
Unidentified crustose coralline	1		crustose coralline
Ventricaria ventricosa	1		
Porites rus	85		
Xestospongia aff. carbonaria	1		
	5		hard bottom
Cyanobacteria	1		
Dictyopteris repens	4		
Dictyota sp.	1		
Halimeda sp.	3		small
Porites rus	88		
Xestospongia aff. carbonaria	1		
	4		hard bottom
Caulerpa filicoides	1		
Caulerpa verticillata	1		
Dictyopteris repens	2		

Halimeda sp.	5		small
Unidentified crustose coralline	1		crustose coralline
Unid. ascidia	2	white	tufted Ascidian
Porites rus	85		
Stylinos ruetzleri	1		
Xestospongia aff. carbonaria	2		
	2		hard bottom
Amphiroa sp.	1		
Caulerpa filicoides	2		
Cryptonemia ? sp.	1		
Dictyopteris repens	4		
Halimeda sp.	2		elongate
Halimeda sp.	4		small
Tydemania expeditionis	1		
Unidentified crustose coralline	1		crustose coralline
Porites rus	85		
Tedania meandrica	1		
Xestospongia aff. carbonaria	2		
	3		hard bottom
Halimeda sp.	6		small
Turbinaria sp.	1		
Polycarpa sp.	1		
Porites rus	85		
Xestospongia aff. carbonaria	3		
	3		hard bottom
Dictyopteris repens	1		
Halimeda sp.	10		small
Tydemania expeditionis	1		
Unidentified crustose coralline	1		crustose coralline
Porites rus	80		
Tedania meandrica	1		
Xestospongia aff. carbonaria	10		
Caulerpa verticillata	1		
Dictyota sp.	1		
Halimeda sp.	10		small
Unidentified crustose coralline	3		crustose coralline
Unidentified sp.	1		ralfsia-like
Rhopalaea sp.	1		
Porites rus	90		
Cyanobacteria	1		
Dictyota sp.	1		
Halimeda sp.	30		small
Unidentified sp.	1		ralfsia-like
Porites rus	70		
Cryptonemia ? sp.	2		
Halimeda sp.	2		
Unidentified sp.	5		ralfsia-like

Porites rus	82		
Haliclona sp. 2	1	blue	
Rhabdastrella globostellata	3		
Unid. sponge	1	white	tufted
Cyanobacteria	1		
Dictyota sp.	3		
Halimeda sp.	12		small
Peyssonnelia sp.	8		
Unidentified crustose coralline	4		crustose coralline
Unidentified sp.	2		ralfsia-like
Porites rus	60		
Ceratopscion sp. 1	3		
Corticium sp. 1	1		
Plakina sp.	1		
	5		hard bottom
Amphiroa sp.	1		
Dictyopteris repens	1		
Dictyota sp.	1		
Halimeda sp.	25		small
Peyssonnelia sp.	7		
Tydemania expeditionis	1		
Unidentified sp.	6		ralfsia-like
Ventricaria ventricosa	1		
Porites rus	37		
Ceratopscion sp. 1	2		
Stylissa massa	1		
	17		hard bottom
Amphiroa sp.	1		
Cryptonemia ? sp.	1		
Cyanobacteria	1		
Dictyopteris repens	1		
Dictyota sp.	1		
Halimeda sp.	10		small
Peyssonnelia sp.	1		
Unidentified crustose coralline	5		crustose coralline
Unidentified sp.	10		ralfsia-like
Porites rus	50		
Ceratopscion sp. 1	2		
Pseudoceratina sp. 1	1		
Unid. sponge	4	white	tufted
	12		hard bottom
Amphiroa sp.	1		
Dictyopteris repens	3		
Dictyota sp.	1		
Halimeda sp.	4		small
Peyssonnelia sp.	1		
Tydemania expeditionis	1		

Unidentified crustose coralline	2		crustose coralline
Unidentified sp.	10		ralfsia-like
Unid. ascidia	1	clear	hard Ascidian
Porites rus	25		
Ceratopscion sp. 1	1		
Pseudoceratina sp. 1	1		
Unid. sponge	10	white	tufted
	39		hard bottom
Bryopsis sp.	1		
Caulerpa filicoides	1		
Dictyopteris repens	1		
Dictyota sp.	3		
Halimeda sp.	8		small
Peyssonnelia sp.	6		
Unidentified crustose coralline	6		crustose coralline
Unidentified sp.	5		ralfsia-like
Porites rus	45		
Plakina sp.	1		
Stylissa massa	1		
	22		hard bottom
Caulerpa verticillata	1		
Cyanobacteria	1		
Dictyopteris repens	6		
Dictyota sp.	2		
Halimeda sp.	14		small
Peyssonnelia sp.	2		
Symploca sp.	1		
Tydemanina expeditionis	1		
Unidentified crustose coralline	2		crustose coralline
Unidentified sp.	8		ralfsia-like
Ventricaria ventricosa	1		
Rhopalaea crassa	1		
Porites rus	50		
Ceratopscion sp. 1	1		
Corticium sp. 1	1		
Plakina sp.	4		
Xestospongia aff. carbonaria	4		
Caulerpa filicoides	1		
Dictyopteris repens	8		
Dictyota sp.	1		
Halimeda sp.	10		small
Peyssonnelia sp.	4		
Tydemanina expeditionis	1		
Unidentified crustose coralline	2		crustose coralline
Unidentified sp.	6		ralfsia-like
Porites rus	30		
Haliclona sp. 2	1	blue	

Plakina sp.	2		
Pseudoceratina sp. 1	1		
Stylissa massa	1		
Unid. sponge	1	red	Clathria-like
Unid. sponge	2	white	tufted
Xestospongia aff. carbonaria	3		
	26		hard bottom
Amphiroa sp.	5		
Caulerpa verticillata	2		
Chondria sp.	1		
Cryptonemia ? sp.	3		
Cyanobacteria	1		
Dictyopteris repens	1		
Dictyota sp.	6		
Halimeda opuntia	4		
Halimeda sp.	25		elongate
Lobophora variegata	2		
Padina sp.	3		
Peyssonnelia sp.	4		
Tydemania expeditionis	2		
Unidentified sp.	8		Ralfsia-like
Galaxea sp.	1		
Pocillopora damicornis	1		
Porites lobata	22		
Porites rus	18		
Sinularia sp.	2		
Xestospongia aff. carbonaria	4

Survey Personnel**Corals**

SLC = Steven Coles

VEB = Victor Bonito

DF = Douglas Fenner

YG = Yimnang Golbuu

Algae and Sessile Invertebrates

JL = Jeffery Landgraf

KL = Katie Laing

SK = Stacey Kilarski

LG = Louise Giuseffi

Mobile Invertebrates

ML = Matthew Lybolt

KS = Keith Spring

For coral size data the number listed is the first number of the pair bracketing the size range

1 = <2 cm

2 = 2 cm to <5 cm

10 = 10 cm to <20 cm

40 = 40 cm to <80 cm
